Data-Intensive Science of Relationships Among Species, Volatile Organic Compounds and Biological Activities¹

Azian Azamimi binti Abdullah

Abstract

Volatile organic compounds (VOCs) are small molecules with low molecular weight that exhibit high vapor pressure under ambient conditions. In this study, we have developed a VOC database of microorganisms, fungi, plants as well as human being, which comprises the relation between emitting species, VOC, and their biological activities. We have deposited the VOC data into KNApSAcK Metabolite Ecology Database and this database is currently available online. Accumulated data are divided into two types: (1) microorganisms species-VOC relations, and (2) emitting species-VOC-biological activity relations. Initially, we performed hierarchical clustering and graph clustering by DPCLUS algorithm to extract clusters of microorganisms based on VOC similarity. Both clustering results indicated that VOC based classification of microorganisms is consistent with their classification based on pathogenicity. For the second data, we performed heatmap clustering utilizing Tanimoto coefficient as the similarity index between chemical structures to cluster all VOCs. We further accessed the statistical significance of the clusters using hypergeometric p -values to understand the relationships between chemical structures of VOCs and their biological activities. Additionally, we also compared several types of hierarchical clustering methods with DPCLUS clustering to classify VOCs using fingerprint-based similarity measure between chemical structures. Our research indicates that similar chemical structures of VOCs indicate possibilities of exhibiting similar biological activities. We extended our findings by using supervised machine learning methods to predict biological activities of VOCs based on chemical structures. We have developed 72 classification models for the prediction of biological activities of VOCs by 9 types of fingerprints and trained by Deep Neural Network (DNN), Gradient Boosting Machine (GBM), Random Forest

(RF) and Generalized Linear Model (GLM). Based on our computational results, PubChem fingerprints trained with GBM method are suggested to be used as the input for the prediction compared to other fingerprints and machine learning methods. Generally, GBM method can outperform DNN in term of classifying VOCs. GBM method has advantage in term of computational speed and requires less parameter for optimization. Hence, we highly recommend using GBM method for the prediction of biological activities of VOCs based on chemical structures.

Keywords: Volatile organic compounds, species, biological activity, clustering

Acknowledgements

First and foremost, I thank Allah, the Lord of the Worlds, the Beneficent, and the Most Merciful, for giving me the light and for enabling me to complete this dissertation. There were many obstacles during this journey, but Alhamdulillah with his help and will, I manage to go through it.

I owe special thanks to my supervisor, Professor Shigehiko Kanaya, for his supervision and continuous support. He always taught me on how to be a good researcher and a scientist.

I also want to express my gratitude for Professor Keiichi Yasumoto for taking his time to review my thesis and for his insightful recommendations.

My thanks go to Associate Professor Md. Altaf-Ul-Amin, Assistant Professor Naoaki Ono and Assistant Professor Tetsuo Sato for all their support, valuable comments and suggestions. I also want to extend particular thanks to Professor Takaaki Nishioka for his knowledge sharing in biochemistry, Associate Professor Tadao Sugiura, and Assistant Professor Ming Huang. I am also grateful to Mrs. Minako Ohashi for her help in administrative matter and Mrs. Aki Hirai Morita for her support in developing KNAPSAcK Family Databases.

I wish to thank all my fellow lab members in Computational Systems Biology Laboratory especially Dr. Sony Hortono Wijaya, Dr. Kibinge Nelson Kipchirchir, Dr. Tetsuo Katsuragi and Ms. Lidwina Ayu Andarini for their support in my studies. I am really grateful for having such a good place for conducting research.

I also would like to express my appreciation to all staff in NAIST International Student Affairs Section for their contribution throughout my studies. I also owe tremendous debt of gratitude to all my friends in Japan and Malaysia for their continuous support and motivation.

I also wish to thank to Universiti Malaysia Perlis and Ministry of Education

Malaysia for their financial support during my doctoral course in Japan. The scholarship has offered me a wide knowledge and new experience.

Last but not least, my special and highest appreciation to all my family members, especially for my parents, Mr. Abdullah Ibrahim and Mrs. Che Mah Yahya for their unconditional love, support and prayers for my success. I also wish to express my gratitude to my late husband, Mr. Ahmad Faiz Ahmad Najah for his last blessing and love. He is my main motivation to undertake and complete this doctoral study. May Allah bless his soul, forgive him of his sins and grant him the highest levels of paradise. Ameen.

Chapter 1

Introduction

This dissertation summarizes the author's research experience in developing a novel volatile organic compound (VOC) database and analyzing the relationships among species, volatile organic compounds and biological activities. This study also attempts to predict the biological activity of volatile organic compound based on their chemical structures by using various machine-learning methods. This chapter describes the general background, the research problem, and research objectives and also explains what are to be expected from the rest of the dissertation.

1.1. Background

Metabolomics is the scientific study of quantification of low mass compounds profiles and analysis of chemical processes involving metabolites in a comprehensive fashion. In general, metabolites can be divided into two groups: primary and secondary metabolites. Primary metabolites are directly involved in the normal growth, development and reproduction. On the other hand, secondary metabolites are not directly involved in these processes, but usually have important ecological functions, such as inter- or intra-species communication, antifungal, antimicrobial activities and also as a defense against pests and pathogens (Agostini-costa et al. 2012). Secondary metabolites are often colored, fragrant, or flavorful compounds and largely fall into three classes of compounds: alkaloids, terpenoids and phenolics. Small proportions produced by these secondary metabolites are volatile organic compounds (VOCs) that play important roles in chemical ecology and human healthcare.

VOCs can be defined as small compounds ranging in between C5 to C20 carbon count with a molecular weight in the range of 50 to 200 Daltons (Rowan

2011). They comprise of a diverse chemical group of organic compounds with various biological functions and have high vapor pressures under ambient conditions. Their high vapor pressure results from a low boiling point, which causes large numbers of molecules to evaporate from the liquid or solid form of the compound and enter the surrounding air, a trait known as volatility. Living organisms including human, animals, microorganisms and plants produce VOCs naturally. The naturally produced VOCs play important roles in communication between plants and they also serve as signaling molecules by passing information between organisms. For human and other animals, VOCs are important as scents and flavor of food. Recently, an increased number of researchers are utilizing VOCs as a biomarker to identify various kinds of diseases. Here, we elaborate further details of the importance of VOCs for living organisms specifically in chemical ecology, agriculture and human healthcare.

(a) Chemical ecology

VOCs constitute only a small proportion of the total number of secondary metabolites produced by living organisms, however, because of their important roles in chemical ecology specifically in the biological interactions between organisms and ecosystems, revealing and analyzing the roles of these VOCs is essential for understanding the interdependence of organisms. The total amount of VOCs emitted globally to the atmosphere is estimated to exceed 1 Pg per year, and these VOCs include mainly plant-produced VOCs, isoprene, monoterpenes and other oxygenated carbon compounds, such as herbivore-induced volatiles and green leaf volatiles (Iijima 2014). Many studies have been performed that showed the emission of VOCs from plants occur as significant cues, signals, or defense responses to wounding, herbivore infestation, pathogen infection, and pollination. The emitted VOCs are responsible for internal and external communication between plants and herbivores, pathogens, pollinators, and parasitoids as shown in Fig. 1.1. Plants emit VOCs from their roots, leaves, fruits and flowers and use

these compounds internally as defensive and signaling systems to induce levels of systemic acquired resistance (SAR) to pests and diseases. Some VOCs, such as methyl jasmonate α -pinene, camphene, and 1,8-cineol may inhibit the growth of other plants. VOCs produced by plant organs such as fruits and flowers also can act as external signaling molecules or semiochemicals by attracting pollinators and seed dispersers (Delory et al. 2016). They also contribute to the attraction of pest insects and beneficial insect predators in tritrophic interactions. Apart from plants, VOCs also act as a major communication among insects and other arthropods. Female insects use specific VOCs as sex pheromones to attract mates (Reddy & Guerrero 2004). Insects also use VOCs to mark pathways between nest and food and for defense (de Bruyne & Baker 2008).

Figure 1.1. *Internal and external communication between plants, herbivores, pathogens, pollinators, and parasitoids (Scala et al. 2013).*

(b) Agriculture

Another important application field of VOCs is agriculture. Conventional agricultural industry relies on a wide use of chemical pesticides and fertilizers. However, increased demand for organic products shows that consumers prefer reduced chemical use. Therefore, a novel sustainable agriculture needs to be developed for crop protection and prevention from using harmful chemicals. VOCs emitted by bacteria and fungi might have the potential as an alternative to the use of chemical pesticides to protect plants from pests and pathogens (Kanchiswamy et al. 2015a). It is because VOCs released by some plant growth-promoting rhizobacteria (PGPR) can enhance plant growth as well as inhibit the growth of other microorganisms, as shown in Fig. 1.2. For example, acetoin and 2,3-butanediol released by rhizobacteria were found to promote the growth of *Arabidopsis thaliana* seedlings (Kai et al. 2016). A number of frequently emitted VOCs such as hexanal and 2-E-hexenal show antifungal activity and have been developed as an alternative to synthetic chemicals (Ayseli & Ipek 2015). Chemical ecologists also consider microbial VOCs as potential signaling molecules or semiochemicals that function as attractants and repellents to insects and other invertebrates. Pheromone traps are VOC based equipment for controlling pests without using harmful pesticides (Beck & Vannette 2016). In this strategy, pest insects may be diverted away from high-value crops using attractants, while simultaneously being repelled from high-value crops with repellents. Furthermore, natural enemies of insect pests, which are predators and parasitoids, may be simultaneously attracted making the use of semiochemicals a much more viable integrated management strategy than broad-spectrum chemical insecticides. For agriculture scientists, microbial VOCs are seen as biocontrol agents to control various phytopathogens and as biofertilizers for plant growth promotion (Kanchiswamy et al. 2015b). Fig. 1.3 shows the combination of two distinct approaches, which are the identification of very early biomarkers using a knowledge base of translational genomic information on host and pathogen

responses and also the development of novel sensors that capture biomarkers for disease detection (Dandekar et al. 2010; Cheung et al. 2015). The authors claimed that it should be possible to identify and defend the crop by interdicting pathogen spread prior to the rapid expansion phase of the disease. These examples indicate that the VOCs might have a potential impact on crop welfare and sustainable agriculture.

Figure 1.2. *The beneficial microbes such as PGPR can enhance plant growth and induce resistance in aerial plant tissues (Pineda et al. 2010).*

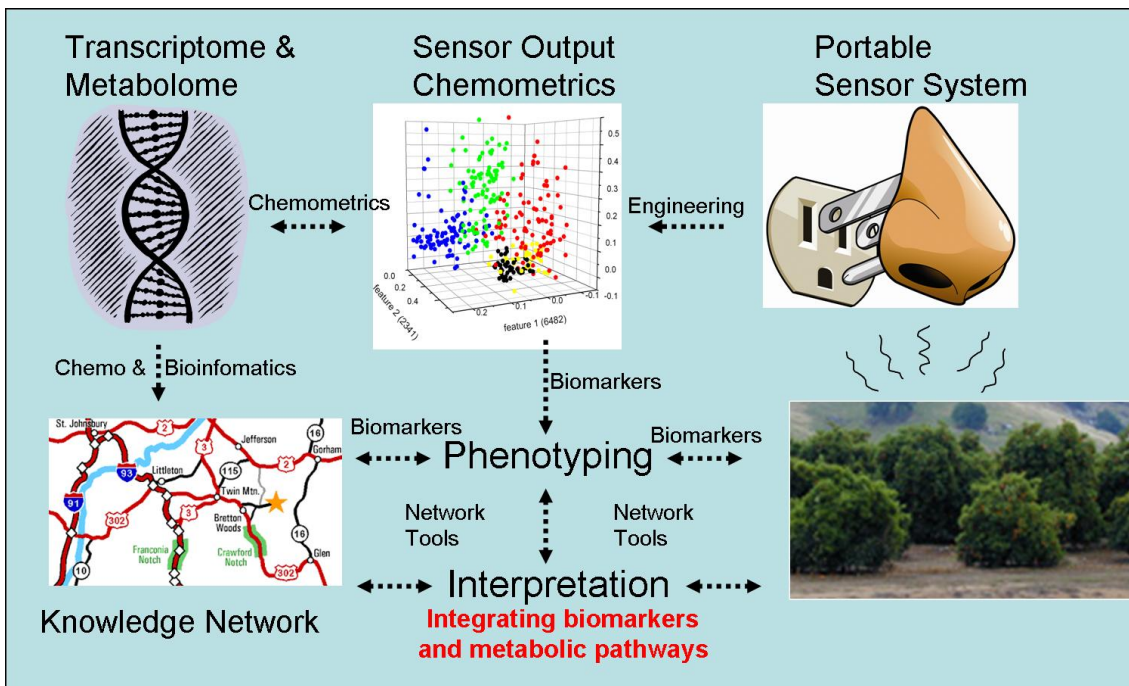

Figure 1.3. *Combination of portable sensor system and bioinformatics knowledge for the management of vector-borne diseases of specialty crops (Dandekar et al. 2010).*

(c) Human healthcare

Recently, there are many research works in applying VOCs as human disease biomarker. This is because the volatiles produced by humans reflect the different metabolic phenotypes (metabotypes) of individuals and may be useful as non-invasive biomarkers to evaluate and monitor disease or health status (Holmes et al. 2008). Hundreds of volatiles are emitted through the human body in breath, blood, skin, fecal and urine as shown in Fig. 1.4 (Shirasu & Touhara 2011; Buljubasic & Buchbauer 2015). A comprehensive review of breath analysis in disease diagnosis using volatile profiles has been presented by (Lourenço & Turner 2014). Breath analysis can be used as a biomarker to identify patients related to breast cancer (Wang, Sun, et al. 2014; Phillips et al. 2010; Phillips et al. 2003), colorectal cancer (Altomare et al. 2013; Amal et al. 2016), pulmonary tuberculosis (Syhre & Chambers 2008; Phillips et al. 2007), and lung cancer

(Hakim et al. 2012; Wang, Dong, et al. 2014; Capuano et al. 2015). Some recent developments of electronic-nose (e-nose) technologies, particularly involving breath analysis, with the potential for providing many new diagnostic applications for the detection of specific human diseases associated with different organs in the body has been summarized by (Wilson 2015). This is also supported by (Fitzgerald et al. 2016), where they stated that the e-nose technology can contribute to personalized medicine approach and have potential to develop early detection for stress-related disorders through analysis of VOCs from exhaled breath. Besides the exhaled breath, fecal and urine headspace VOCs also can be used to diagnose gastrointestinal illness (Garner et al. 2007; Probert et al. 2009; Arasaradnam et al. 2014; Chan et al. 2016).

Figure 1.4. *Hundreds of VOCs are emitted through the human body (Shirasu & Touhara 2011).*

Microbial volatiles are also widely used as biomarkers to detect human diseases. This is because bacteria have a recognizable metabolism that produces bacteria-specific VOCs, which might be used for non-invasive diagnostic purposes (Bos et al. 2013). For example, an electronic nose has been used to determine the causative bacteria responsible for diabetic foot infection by recognizing its volatiles (Yusuf et al. 2015). Recently, some authors reported that skin microbiota may play a major role in human attractiveness to blood-sucking insects (Verhulst et al. 2010; Dormont et al. 2013). These insects are responsible for transmission of widespread and sometimes deadly infectious diseases, including malaria (Wong et al. 2012; De Moraes et al. 2014), dengue (Paixão et al. 2014) and zika virus (Didier Musso 2016). These examples indicate that disease-specific VOCs have potential as diagnostic olfactory biomarkers of infectious diseases, metabolic diseases, genetic disorders and other kinds of diseases.

1.2. Research Problem and Objectives

Advancements in analytical methods such as gas chromatography mass spectrometry (GCMS), proton transfer reaction mass spectrometry (PTR-MS), and selected ion flow tube mass spectrometry (SIFT-MS) have provided an opportunity to identify the volatile metabolites of living organisms in research laboratories. These analytical approaches generate a large amount of data and require specialized mathematical, statistical and bioinformatics tool to analyze such data. Despite the advances in sampling and detection by these analytical methods, only few databases have been developed to handle these large and complex datasets. For example, the Superscent database (Dunkel et al. 2009) only provides structure information of flavors and scents, and the mVOC database (Lemfack et al. 2014) provides information of microbial volatiles only. Flavornet (Arn & Acree 1998) features compounds identified in experiments employing gas chromatography olfactometry (GC-O) analysis, and Pherobase (El-Sayed 2014) is focused on insect pheromones and semiochemicals. The vocBinBase (Skogerson et al. 2011) is a

mass spectral database for volatiles which can allow for tracking and identification of volatile compounds in complex mixtures. None of these databases provide information on biological activities of VOCs and species-species interaction based on volatiles. Information on volatiles emission from microorganisms, plants, and other organisms is scattered in the literature, but there is no public and up-to-date database that accumulated comprehensive information of volatiles and their biological activities. To meet this purpose, we attempt to develop a novel VOC database that accumulates information of emitting species, VOC and biological activities. The main objective of this study is to explore and identify the diversity roles of volatile organic compounds emitted by various species such as plants, microorganisms and human and also to develop a novel database of VOCs extracted from the literature. Second objective is to analyze the relationships between VOCs and microorganisms species based on VOC similarity by using clustering methods. The third objective is to analyze the relationships between other species, VOCs and biological activities based on chemical structural similarity by using unsupervised and supervised machine learning methods.

1.3. Dissertation outline

This dissertation outline is organized as follows. In Chapter 2, the development of VOC database and information on accumulated data is explained. We explain on how potential user can utilize this database for systematic studies in metabolomics. Chapter 3 describes hierarchical clustering and network clustering based on DPCLUS algorithm for classifying the microorganism species based on VOC metabolites content similarity. In Chapter 4, we discussed on heatmap clustering based on Tanimoto coefficient as the similarity index between chemical structures to cluster all VOCs emitted by other biological species. The resulted clusters were then further accessed by p -value based on hypergeometric

distribution to understand the relationships between chemical structures of VOCs and their biological activities. Then, we also compared several different clustering methods to determine the degree of cluster overlap and how well it classified chemical structures of VOCs into clusters. Additionally, we extended our analysis by implementing supervised machine learning methods such as Deep Neural Network (DNN), Gradient Boosting Machine (GBM), Random Forest (RF) and Generalized Linear Model (GLM) using different type of molecular fingerprints as classification models for predicting the biological activities of VOCs based on their chemical structures. Finally, Chapter 5 gives concluding remarks of this dissertation.

Chapter 2

Development of a VOC Database

2.1. Background

Recently big data has become an important topic that has significant roles to play in versatile disciplines of scientific research. Big data biology is a data-intensive science, which has emerged because of the rapidly increasing volume of molecular biological data in omics fields such as genomics, transcriptomics, proteomics and metabolomics (Hey et al. 2009; Kelling et al. 2009; Patterson et al. 2010). With the explosively growing data scale, the development of biological databases incorporating different species has become a very important theme in big data biology. To address this need, we have developed KNApSAcK Family Databases (DBs), which have been utilized in a number of studies in metabolomics. The KNApSAcK Family database systems previously have been used to understand the medicinal usage of plants based on traditional and modern knowledge (Afendi et al. 2012; Afendi et al. 2013; Wijaya et al. 2014). A review of the KNApSAcK DB utilization in scientific work is presented by (Ikeda et al. 2013). Data also has been accumulated in the KNApSAcK DB in order to facilitate the comprehensive understanding of healthy cuisine ingredients, as well as metabolomics (Katsuragi et al. 2013). To facilitate a comprehensive understanding of the interactions between the metabolites of organisms and the chemical-level contribution of metabolites to human health, a metabolite activity DB known as the KNApSAcK Metabolite Activity DB has been constructed (Nakamura et al. 2013; Nakamura et al. 2014) and a network-based approach has been proposed to analyze the relationships between 3D structure and biological activities of the metabolites (Ohtana et al. 2014).

In this study, we have developed a VOC database of microorganisms, fungi, and plants as well as human being, which comprises the relation between

emitting species, VOC and their biological activities (Abdullah et al. 2015). We have deposited the VOC data into KNApSAcK Metabolite Ecology Database, a part of KNApSAcK family databases and this database is currently available at <http://kanaya.naist.jp/MetaboliteEcology/top.jsp>. In this chapter, we describe the development of a VOC database and explain how potential users can utilize this database for metabolomics studies.

2.2. Methods

The data were collected by an extensive literature search on PubMed (<http://www.ncbi.nlm.nih.gov/pubmed>) and Google Scholar. The PubMed search provided more than 100 articles based on the keywords “volatile organic compounds” and “metabolites”. The information on VOCs, emitting species, target species and their biological activities were extracted and deposited into KNApSAcK Metabolite Ecology Database. The KNApSAcK Metabolite Ecology is also linked to the KNApSAcK Core and KNApSAcK Metabolite Activity databases to provide further information on the metabolites and their biological activities. Data were divided into two types: 1) Microorganisms species – VOC binary relations, 2) Emitting species – VOC – biological activities triplet relations.

2.3. Results and Discussion

At present, we have accumulated 1088 VOCs emitted by 517 microorganisms species and 341 VOCs emitted by other biological species including plants, fungi, animals and human with their related biological activities. These VOC data have been deposited into KNApSAcK Metabolite Ecology Database, which allows users to search information on VOCs using the KNApSAcK compound ID and metabolite name. The main window of KNApSAcK Family Databases is shown in Fig. 2.1 and user can access the KNApSAcK Metabolite Ecology Database by clicking the corresponding button.

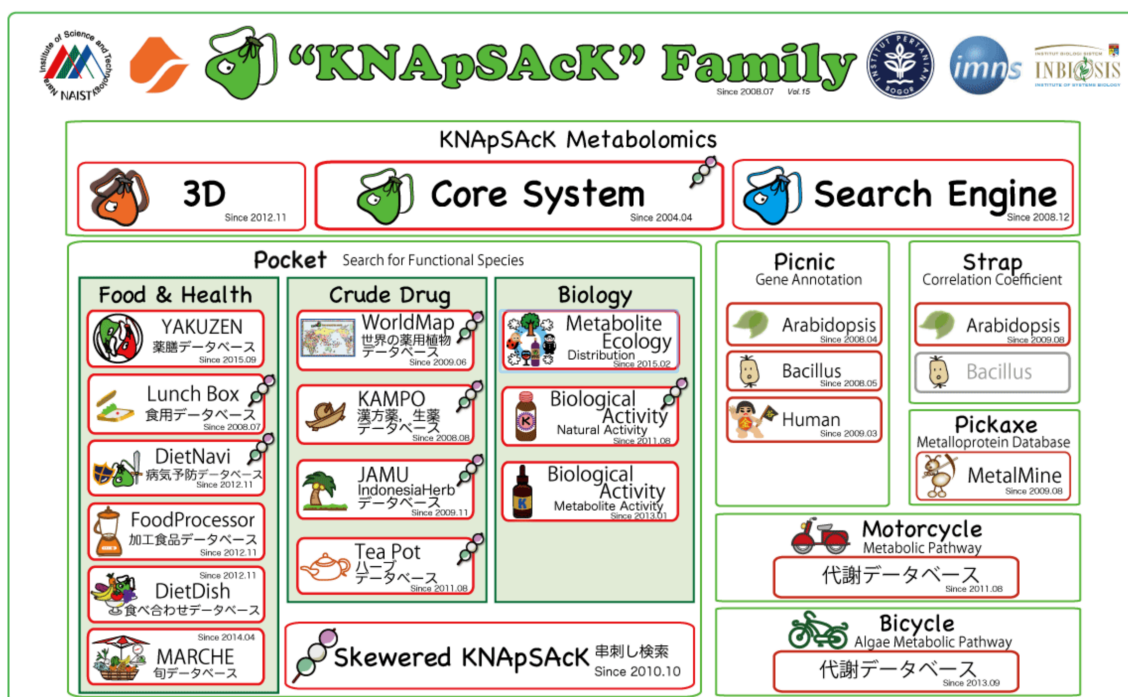

Figure 2.1. The main window of the KNApSAcK Family Databases.
(http://kanaya.naist.jp/KNApSAcK_Family/)

Figure 2.2 shows the main window of the KNApSAcK Metabolite Ecology Database, which shows the search types and search conditions. For search type, users can choose either partial or exact string matching searches by clicking the corresponding button, i.e. Partial or Exact (Fig. 2.2A). Other check boxes can also be selected to specify different search conditions (Fig. 12.2B) such as KNApSAcK compound ID (C_ID), metabolite name, species name and ecological category or localization. To search VOC data, users can input 'VOC' in the text box for the Ecological category/Localization category, select the corresponding checkbox and then click the List button (Fig. 2.2C).

In Metabolite Ecology DB, users can search for metabolites--

(i) Belong to certain ecological category (e.g. VOC)
Example : C_ID: C00000805/Metabolite name: Alpha-Pinene/ Ecological category: VOC

(ii) Available at certain plant localization (e.g. Leaf, Root, Rhizomes)
Example : C_ID: C00001176/Metabolite name: Acetic Acid/ Plant localization :Rhizomes

Metabolite Ecology Keyword Search

Search Type Partial
 Exact

Decide search conditions by selecting the appropriate checkboxes (AND search).

C_ID (Exact only)

Metabolite Name

Species Name

Ecological category/Localization

Figure 2.2. The main window of the KNApSAcK Metabolite Ecology Database.

Part of the result retrieved by entering ‘VOC’ in the text box is shown in Fig. 2.3. The attributes in the list are C_ID, which corresponds to the KNApSAcK compound ID, metabolite name, species name (VOCs emitting species), ecological category/localization (VOC) and references (the source of the VOC’s information), from left to right. As an example, the metabolite known as alpha-Eudesmol (C_ID C00000163) is emitted by *Polygonum minus*, generally known as ‘kesum’ in Malaysia. This particular plant is among the most commonly used food additive, flavoring agent and traditionally used to treat stomach and body aches (Christopher et al. 2014; Vikram et al. 2014). Information related to the VOCs that have KNApSAcK compound ID can be obtained by clicking the C_ID as in Fig. 2.3. Figure 2.4 shows the search results obtained by clicking the C_ID,

C00000163, which were retrieved from the KNApSAcK Core Database. Users can retrieve further knowledge of this metabolite, such as molecular formula, molecular weight, CAS RN, 3D structure, InChIKey and other species information, which also produce the corresponding metabolite.

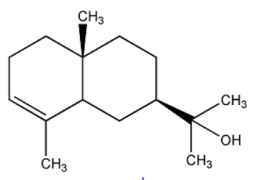

INPUT WORD = [Match Type : Partial , Ecological category/Localization : VOC]

To understand the relationships between VOCs and their biological activities, we also integrate the KNApSack Metabolite Ecology Database with KNApSack Metabolite Activity Database. Information on biological activities of VOCs can be obtained by clicking the 'A' button in Fig. 2.3. Figure 2.5 shows the search result of biological activities related to C_ID C00000163, which was retrieved from the KNApSack Metabolite Activity Database. The attributes in the list are C_ID, metabolite name, activity category, biological activity (function), target species and references, from left to right. From the database, user can find out that this particular VOC, known as alpha-Eudesmol has been emitted by

Polygonum minus and have several biological activities such as anticholinesterase, antimicrobial, antioxidant and allelopathic against target species (*Bacillus cereus*, *Enterococcus faecalis*, *Methilin-resistant Staphylococcus aureus* (MRSA), *Salmonella entiriditis*). This information might be useful for the discovery of novel agriculture tools, as well as the development for market of pharmaceutical agents in the future.

2.4. Summary

In this chapter, we described on the development of a VOC database and explained how to utilize this database for metabolomics studies. Initially, data were accumulated by an extensive literature search through PubMed and Google Scholar. Information on VOCs, emitting species, target species and related biological activity were identified and extracted into an excel format. The data then, were deposited into KNApSAcK Metabolite Ecology Database. Until now, we

have accumulated about 1088 VOCs emitted by microorganisms species and 341 VOCs by other biological species such as plants, insects as well as human with the corresponding biological activities. Apart from VOC biological activities related to human healthcare, more than half of the biological activities are associated with chemical ecology. The KNApSAcK Metabolite Ecology Database may be useful for the discovery of novel agricultural tools by focusing on the identification of plant growth promoting rhizobacteria and also the discovery of signature volatiles of plant pathogenic species. This database also can be utilized for the non-invasive identification of biomarkers in the medical diagnostic field as well as a systematic research in various omics fields, especially metabolomics integrated with ecosystems.

Chapter 3

Clustering of Microorganisms Species Based on VOC Similarity

In previous chapter, we described the development of a novel VOC database, which is known as KNApSAcK Metabolite Ecology Database. There were two types of accumulated data: 1) Microorganisms species – VOC relations, 2) Emitting species – VOC – biological activity relations. This chapter focuses on the clustering analysis result of the first type of data, which are the relationships between microorganism species and their emitting VOCs. Until now, we have accumulated 1088 VOCs emitted by 517 microorganisms species (Abdullah et al. 2015).

3.1. Background

A microorganism or microbe is a microscopic living organism, which may be single-celled (Madigan 2012) or multicellular. They are universal in the biosphere and are often found in large quantities and diverse compositions (microbiome). Microorganisms are very diverse and include all bacteria, archaea and most protozoa. This group also contains some species of fungi, algae, and certain microscopic animals, such as rotifers. Microorganisms are also exploited in biotechnology, both in traditional food and beverage preparation, and in modern technologies based on genetic engineering. A small proportion of microorganisms are pathogenic, causing disease and even death in plants and animals (Alberts et al. 2002).

It is well known that microbes produce a diversity of natural compounds, e.g. antibiotics. Many of these small molecules (<300 Da) exhibit high-vapour

pressures and low boiling points, and, together with a lipophilic character, these features support volatility, which are known as VOCs. In the past decade, studies on microbial volatile organic compounds (mVOC) attracted many researchers (Korpi et al. 2009; Piechulla & Degenhardt 2014; Lemfack et al. 2014). The aromas of wines, cheese and other milk product, which are usually recognized as pleasant by human are resulted from volatiles produced by microorganisms. On the other hand, microorganisms also produce the unpleasant malodorous smells during the process of putrefaction such as amines, indole, sulphur compounds and ammonia. The earthy and muddy smell of wet forest soils is due to the emission of the volatile geosmin released by *Streptomyces* species (Gerber 1967; Cane et al. 2006). The human microbial flora at any given anatomical site is relatively specifically accompanied by a typical volatile organic compound (VOC) profile such as gases released by the gut, foot odour and sweat smell. The VOC mixture of breath originates from more than one source within the respiratory system and respiratory disorders can result in odorous gases being expelled into the air, which can be useful for diagnostic purposes (Cheepsattayakorn & Cheepsattayakorn 2013). For example, a compound known as methyl nicotine can be a promising biomarker to be used as a non-invasive diagnostic tool for detection of *Mycobacterium tuberculosis* (Syhre & Chambers 2008). The emission of 2-nonanone of *Pseudomonas aeruginosa* VOCs may be used as in vivo marker to detect lung infections (Carroll et al. 2005). A group of researchers has investigated the performance of electronic nose (e-nose) technique performing direct measurement of static headspace with algorithm and data interpretations which was validated by GC-MS, to determine the causative bacteria responsible for diabetic foot infection based on their volatiles (Yusuf et al. 2015). Other than diagnostic tool, some volatile compounds produced by microorganisms such as higher alcohols (2-methyl-1-butanol, 3-methyl-1-butanol and isobutanol) can be used as biofuels (Blombach & Eikmanns 2011). Metabolic engineering can be used to improve the production of natural microbial alcohols for the bio renewable fuels

(Ingram et al. 2010; Nozzi et al. 2014; Lee et al. 2015). More than 10 000 microbial species are described and at least a million are expected to exist on earth, the VOC profiles of a surprisingly small number of microorganisms were investigated so far. Considering the importance and the central roles of VOCs in our biosphere, our first objective was to accumulate the data related to VOCs and their emitting microorganisms species. Using this accumulated data, we performed hierarchical clustering and graph clustering for classifying the VOC emitting species based on volatile metabolite content similarity.

3.2. Datasets

We used the first type of data, which are 1088 VOCs emitted by 517 microorganisms species, as mentioned in Chapter 2. The information of emitting species and volatile compounds has been converted into a 517×1088 binary matrix (“1” indicates presence while “0” indicates absence), where rows represent as microorganism species and columns represent VOCs emitted by the corresponding species as shown in Table 2.1. The binary matrix then, was used to calculate the distance between species and to perform the clustering.

Table 2.1. *Representation of microorganism species and volatile organic compounds as a two-dimensional binary matrix.*

Species	VOCs					
	VOC ₁	VOC ₂	VOC ₃	VOC ₄	...	VOC _M
S ₁	1	0	1	1	...	0
S ₂	1	1	0	0	...	0
S ₃	0	1	0	1	...	0
...
S _N	1	0	0	0	...	1

3.3. Methods

Clustering is an unsupervised learning method, which is the task of grouping a set of objects into groups (clusters) based on similarity or distance measures (Jain et al. 1999). This technique is important for knowledge discovery and has been applied in many applications such as machine learning, pattern recognition, image analysis and bioinformatics (Thalamuthu et al. 2006; Diao et al. 2011; Clifford et al. 2011; Richard et al. 2013). The goal of clustering is to determine the intrinsic grouping in a set of unlabeled data. There are many clustering methods based on different algorithms. Typical cluster models include:

(1) Connectivity models: for example, hierarchical clustering builds models based on distance connectivity.

(2) Centroid models: for example, the k-means algorithm represents each cluster by a single mean vector.

(3) Distribution models: clusters are modeled using statistical distributions, such as multivariate normal distributions used by the Expectation-maximization algorithm.

(4) Density models: for example, DBSCAN and OPTICS defines clusters as connected dense regions in the data space.

(5) Subspace models: in Biclustering, clusters are modeled with both cluster members and relevant attributes.

(6) Group models: some algorithms do not provide a refined model for their results and just provide the grouping information.

(7) Graph-based models: a subset of nodes in a graph such that every two nodes in the subset are connected by an edge can be considered as a prototypical form of cluster.

In this study, we utilized hierarchical clustering and graph clustering methods for classifying the VOC emitting species. Both methods are discussed separately in the following:

3.3.1. Hierarchical clustering

We used hierarchical agglomerative clustering method, which starts out by putting each observation into its own separate cluster (Johnson 1967; Murtagh & Contreras 2011; Murtagh & Contreras 2012). The result of clustering is usually represented by a dendrogram. The reason why we choose hierarchical clustering is that, it is easy to use and our objective is to find a specific group for microorganism species. In our case, we used a Species vs. VOC matrix. Let this matrix be called M and $M_{ik}=1$ if the species i is related to the k th VOC or otherwise $M_{ik}=0$. Hierarchical methods require a distance matrix, and hence we determined the Euclidean distances between species. Euclidean distance, d between species i and species j can be calculated as equation (3.1):

$$d(i, j) = \sqrt{\sum_{k=1}^n (M_{ik} - M_{jk})^2} \quad (3.1)$$

Here, n is the number of VOCs, and there are 1088 VOCs in our data. Based on Euclidean distance, we performed the Ward's hierarchical clustering analysis using R, an open-source programming language.

3.3.2. Graph clustering based on DPCLUS

DPCLUS is a graph clustering software (Md. Altaf-Ul-Amin et al. 2006), which has been developed based on a graph-clustering algorithm that can extract densely connected nodes as a cluster (Md Altaf-Ul-Amin et al. 2006). Initially, the

algorithm was purposely developed to detect and visualize clusters of proteins in interaction networks which mostly represent molecular biological functional units. We explore the possibility of this algorithm to other applications as well and here, we apply the DPCLUS algorithm to find a cohesive group for our accumulated microorganism data. This algorithm can be applied to an undirected simple graph $G = (N, E)$ that consists of a finite set of nodes N and a finite set of edges E . Two important parameters are used in this algorithm: density d_k and cluster property cp_{nk} . Density d_k of any cluster k is the ratio of the number of edges present in the cluster ($|E|$) and the maximum possible number of edges in the cluster ($|E|_{max}$). Equation (3.2) represents the cluster property of node n with respect to cluster k :

$$cp_{nk} = \frac{E_{nk}}{d_k \times N_k} \quad (3.2)$$

N_k is the number of nodes in cluster k . E_{nk} is the total number of edges between the node n and the nodes of cluster k . In this study, we applied the DPCLUS algorithm to identify certain groups of microorganism species, based on VOC similarity. A network was constructed where a node represents a microorganism species, and an edge indicates high VOC similarity between the corresponding species pair. We selected 5% of the organism pairs based on the lower Euclidean distance between them. We used the non-overlapping mode with the following DPCLUS settings: Cluster property cp_{nk} was set to 0.5, density value d_k was set to value in between 0.6 and 0.9, and minimum cluster size was set to 2, as recommended by (Md Altaf-Ul-Amin et al. 2006).

3.4. Results and discussion

3.4.1. Hierarchical clustering result

Fig. 3.1 shows the log-log relation between the number of VOCs, M and the frequency of species, N . The pattern roughly follows power-law (Jeong et al. 2001). From this figure, we can see that there are 92 species that emit only one type of VOC (Point x). Highest 50 types of VOCs are emitted by an individual species and there are 14 such species in our present data (Point y). From this statistical analysis, we can say that most microorganism species emit a few VOCs, which can act as their odor fingerprint. The information of emitting species and compounds has been converted into a 517×1088 binary matrix (“1” indicates presence while “0” indicates absence). The binary matrix then, was used to calculate the Euclidean distance between species. From the Euclidean distance, hierarchical clustering of species was performed. Fig. 3.2 shows a hierarchical dendrogram plot of microorganism species based on VOC presence. Here, we cut the dendrogram tree to 50 clusters and the threshold height for this clustering is 7. We also enlarged the clusters that consisting 100% pathogenic microorganisms species, which are clusters 35, 40 and 47.

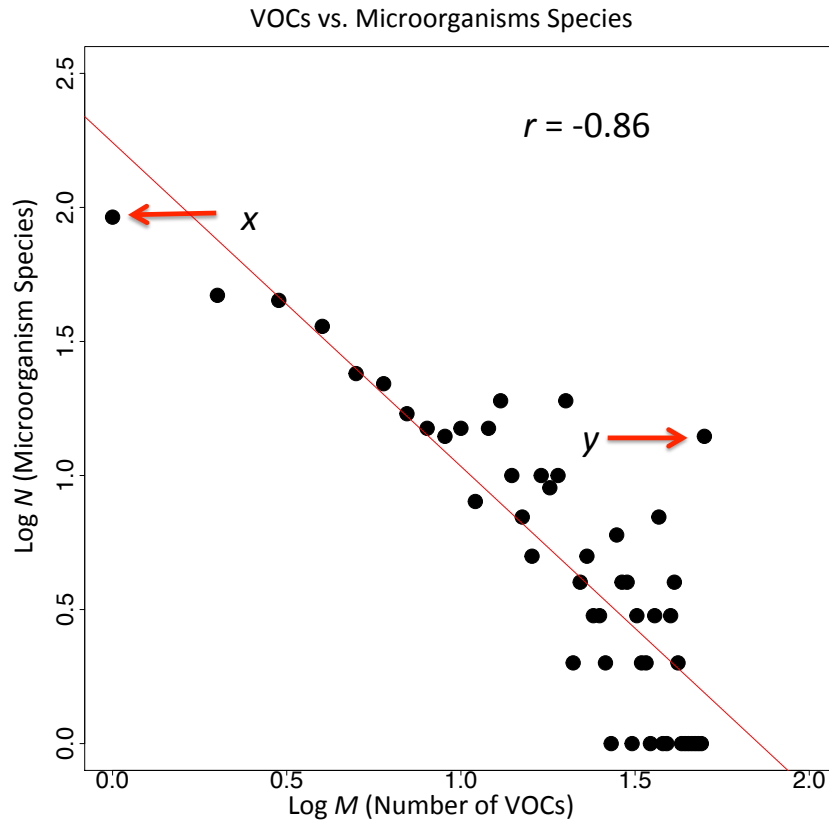

Figure 3.1. The log-log relation between the number of VOCs and the number of related microorganisms species.

Table 1 shows the species name with their corresponding clusters and the pathogenicity of the microorganism species. Interestingly, 77 species from 517 species are known as pathogenic bacteria and are classified into six clusters, which are clusters 6, 27, 35, 40, 47 and 48. Out of these six clusters, three clusters i.e. clusters 35, 40 and 47 (Fig. 3.2) contain 100% pathogenic bacterial species such as *Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *Escherichia coli*. The other three clusters contain both pathogenic and non-pathogenic species. For example, cluster 6 consists of 11 (7.2%) pathogenic bacterial species while cluster 27 comprises of only one (7.7%) pathogen species. Cluster 48 contains 4 (16%) pathogenic bacterial species. Out of all 50 clusters, the rest of 44 clusters contain

non-pathogenic species. These results imply that VOCs emitted by some pathogenic bacteria are different from those emitted by non-pathogenic bacteria. These results show consistency between VOC and pathogenicity-based classification of microorganisms.

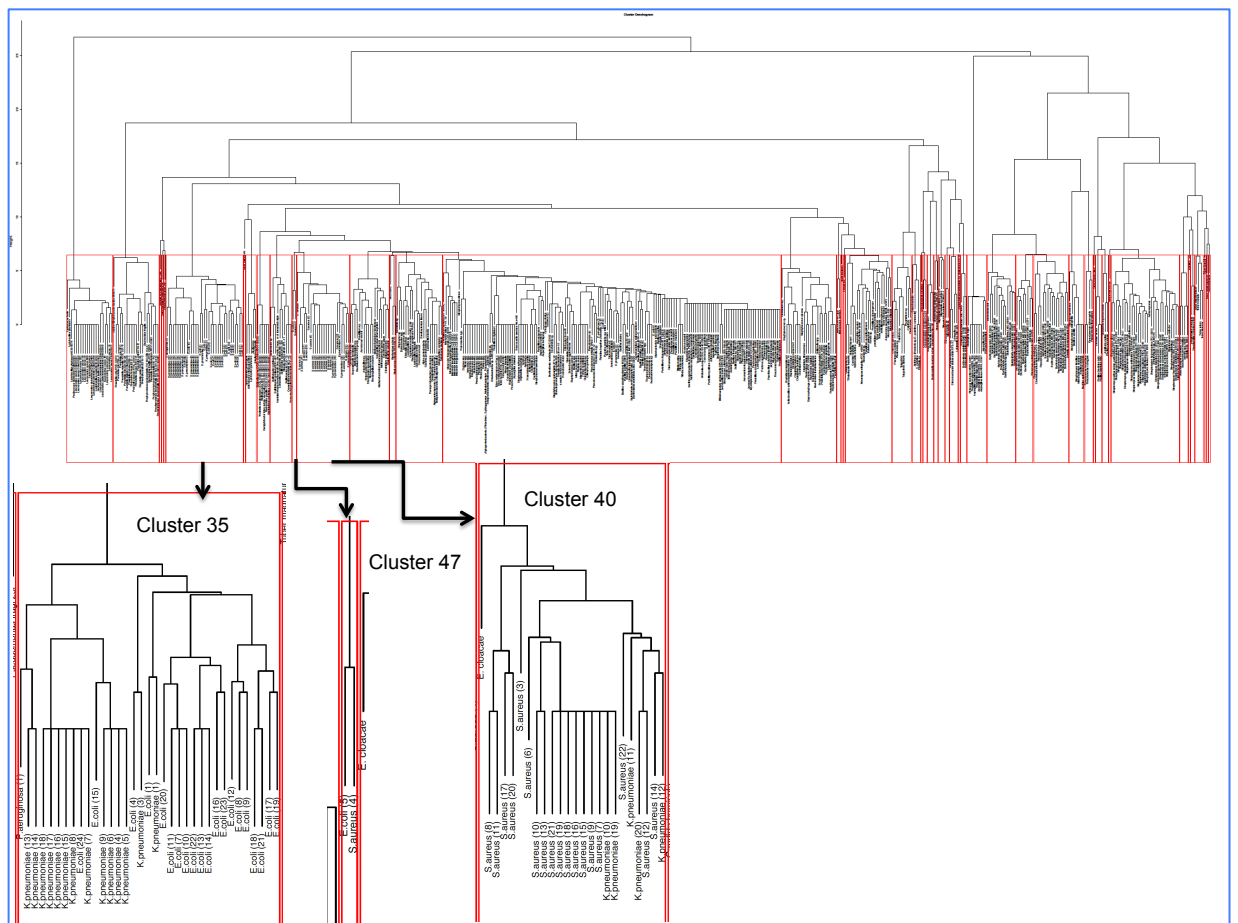

Figure 3.2. Hierarchical dendrogram plot of microorganism species based on VOC similarity. Cluster 35, 40 and 47 contain 100% pathogenic species and the detail description on each cluster with the related microorganisms species is given in Table 3.1.

3.4.2. Graph-clustering based on DPCLUS result

In order to extract different and more information, we constructed a network by inserting edges between species for which the Euclidean distance is less than a threshold. The threshold was decided to include the lowest 5% distances as edges in the network. We then determined the high-density clusters in that network by applying the graph-clustering algorithm DPCLUS. Fig. 3.3 shows the overall network, which displays all the generated clusters in such a way that intra cluster edges are green and inter cluster edges are red. Fig. 3.4 (a) shows the hierarchical connected graph of the clustering result, where the green nodes represent clusters of microorganism species and the red edges represent the interaction between clusters. The radius of a green node in the hierarchical graph in Fig. 3.4 is proportional to the logarithm of the number of nodes in the cluster it represents. The width of a red edge in the hierarchical graph between a pair of clusters is proportional to the number of edges between those clusters in the original graph. Nodes enclosed by dotted rectangle are consisting of only pathogenic bacteria, the only node enclosed by the dotted circle is consisting of both pathogenic and non-pathogenic bacteria and the rest nodes are consisting of only non-pathogenic bacteria. Fig. 3.4 (b) shows the independent nodes of the hierarchical graph, which indicates that these

clusters do not interact with other clusters.

Overall, DPCLus generated 50 clusters where 20 clusters are connected nodes to each other while the rest 30 clusters are independent nodes. Only cluster 1 contains both pathogenic and non-pathogenic microorganisms. Clusters 2, 7, 14, 21, 26 and 40 consist of only pathogenic bacteria while the other clusters are consisting of only non-pathogenic bacteria. These results imply that pathogenicity of microorganisms can be linked to characteristic combinations of identical VOCs emitted by them. Some of the pathogenic members of cluster 1 such as *Klebsiella pneumoniae*, *Escherichia coli*, *Staphylococcus aureus* and *Pseudomonas aeruginosa* are very highly connected to other pathogenic clusters e.g. cluster 2 and 7.

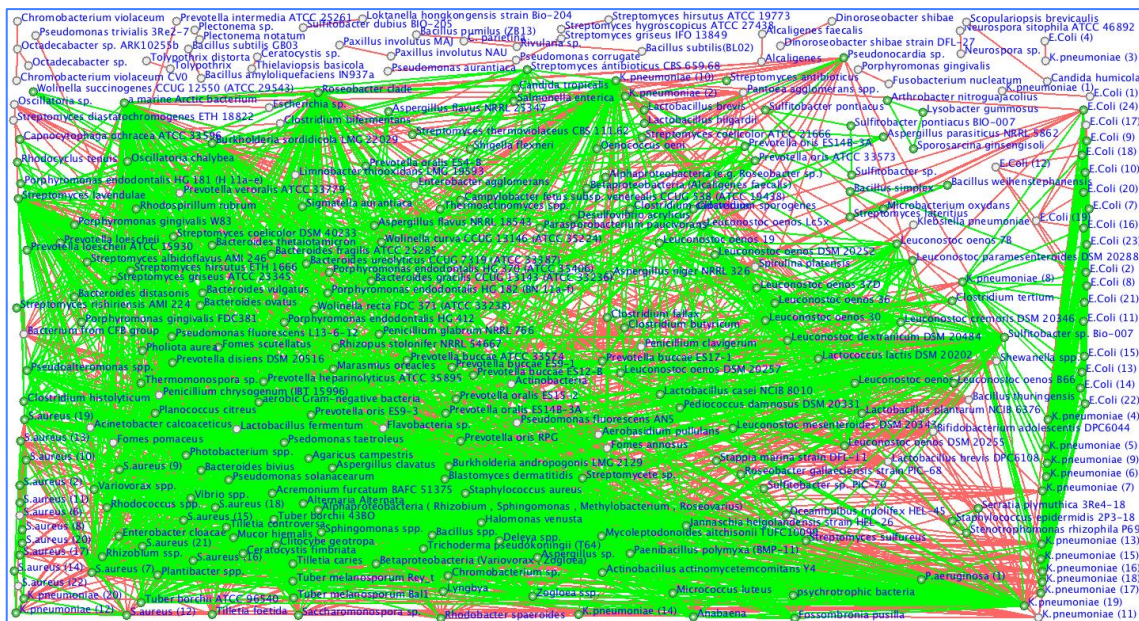

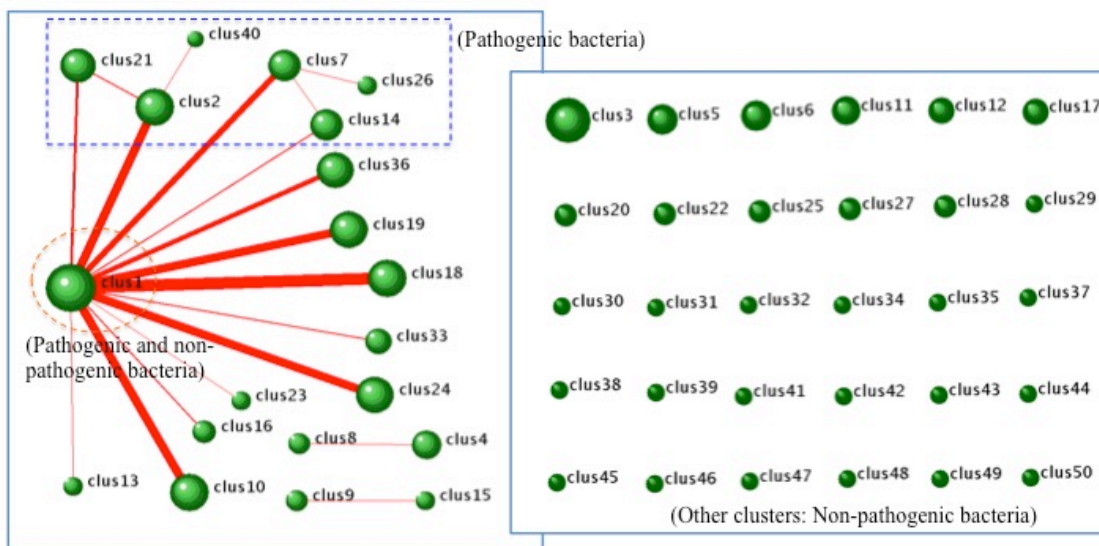

Figure 3.3. Overall DPCLus network, which displays all the generated clusters.

(a)

(b)

Figure 3.4. Hierarchical graph of DPCLUS clustering result in case of $cp_{in} = 0.5$ and $d_{in} = 0.6$. (a) Connected nodes. (b) Independent nodes.

Fig. 3.4 (a) shows that cluster 2, 7, 14, 21, 26 and 40 are connected by red edges, which reflect VOC similarity between pathogenic microorganisms. Also, there are VOC based similarity between non-pathogenic species of cluster 1 and clusters 10, 13, 16, 18, 19, 23, 24, 33 and 36. The red edges between cluster 4 and 8 and between cluster 9 and 15 are also because of VOC similarity between non-pathogenic species of those clusters. Here it is noteworthy that the rest of 30 clusters consisting of non-pathogenic species are independent clusters, which implies that many non-pathogenic groups of species emit quite unique types of VOCs as shown in Fig. 3.4 (b).

Fig. 3.5 shows the microorganism species belong to cluster 1 (pathogenic and non-pathogenic), cluster 7 (pathogenic only) and cluster 10 (non-pathogenic species only), respectively. Here the internal nodes of a cluster are shown connected by green edges and its neighboring clusters are shown connected by red edges. To evaluate the stability of graph-clustering results by DPCLUS, we also clustered the networks generated by several random samplings of 80% or more edges of the original network. We found that DPCLUS can still cluster the microorganisms species based on pathogenicity.

Here, we also examined different values of density, d_{in} to the clustering result. We used $cp_{in} = 0.5$ and $d_{in} = 0.6$ for the experiments discussed in Fig. 3.4 and Fig. 3.5. However the variation of density value, d_{in} can also affect the outcome of the clustering. Fig. 3.6, Fig. 3.7 and Fig. 3.8 show the hierarchical graph of DPCLUS clustering for $d_{in} = 0.7$, $d_{in} = 0.8$ and $d_{in} = 0.9$, respectively. If high value is used for d_{in} , the generated clusters are of high density but smaller in size and hence relatively more in number. 51 clusters were generated for $d_{in} = 0.7$, 52 clusters were generated for $d_{in} = 0.8$, and 55 clusters were generated for $d_{in} = 0.9$. However, many such clusters are consisting of only two, three or four pathogenic microorganisms. The highest number of clusters containing pathogenic clusters ≥ 4 is obtained in case of $cp_{in} = 0.5$ and $d_{in} = 0.6$. Hence, the classification results between pathogenic and non-pathogenic microorganism species are best obtained in case of $cp_{in} = 0.5$ and $d_{in} = 0.6$. In general, from the periphery tracking point of view, we consider that a reasonable and balanced value for cp_{in} is 0.5 and $d_{in} = 0.6$ because it is in the middle of the parameter space. However it can be said that the larger the value of cp_{in} and d_{in} the more spherical the structure of the generated complexes (Md Altaf-Ul-Amin et al. 2006).

Figure 3.5. The three example clusters of microorganism species that classify the microorganism species according to their pathogenicity.

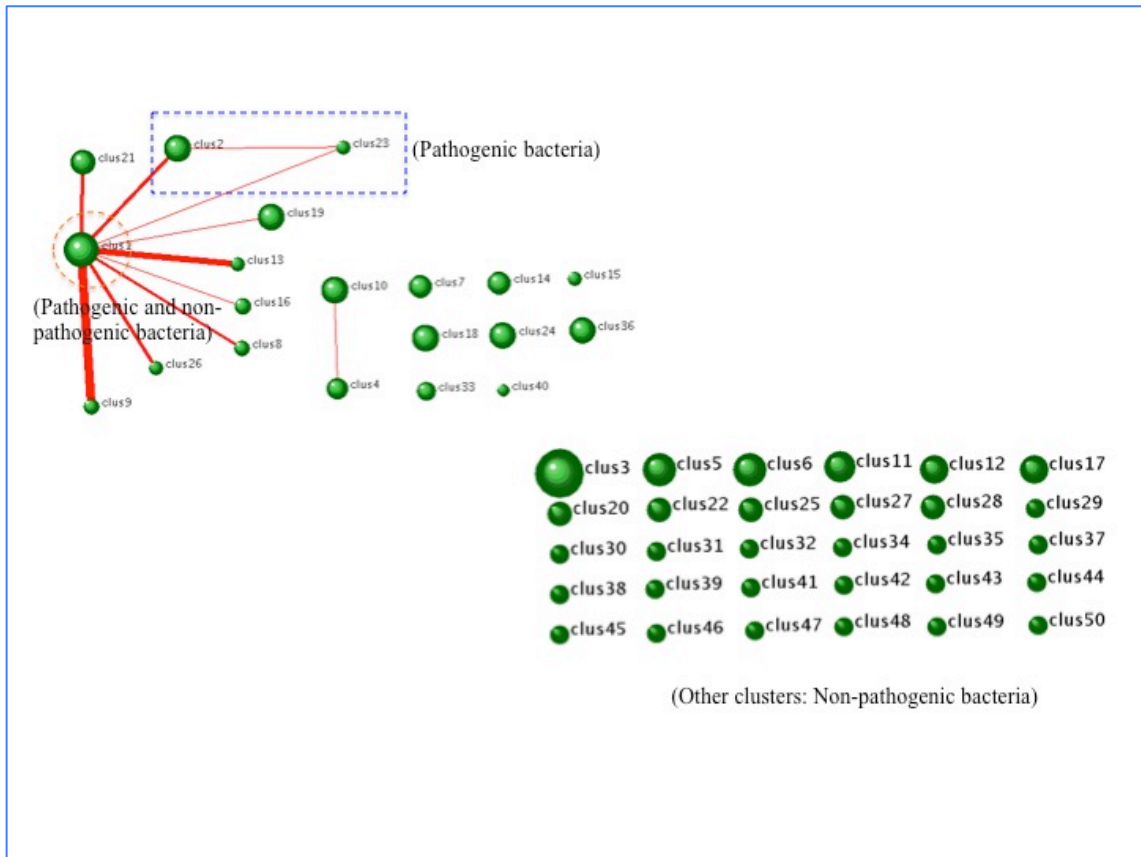

Figure 3.6. Hierarchical graph of DPCLUS clustering result in case of $cp_{in} = 0.5$ and $d_{in} = 0.7$.

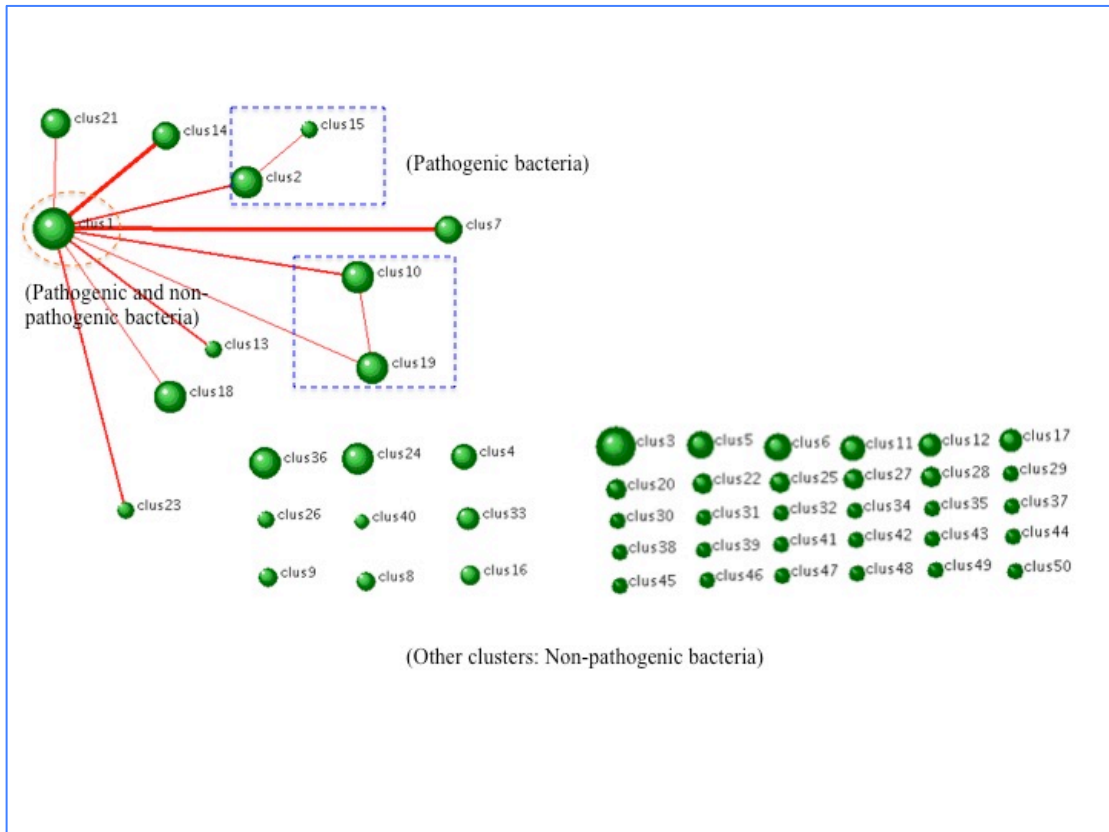

Figure 3.7. Hierarchical graph of DPCLUS clustering result in case of $cp_{in} = 0.5$ and $d_{in} = 0.8$.

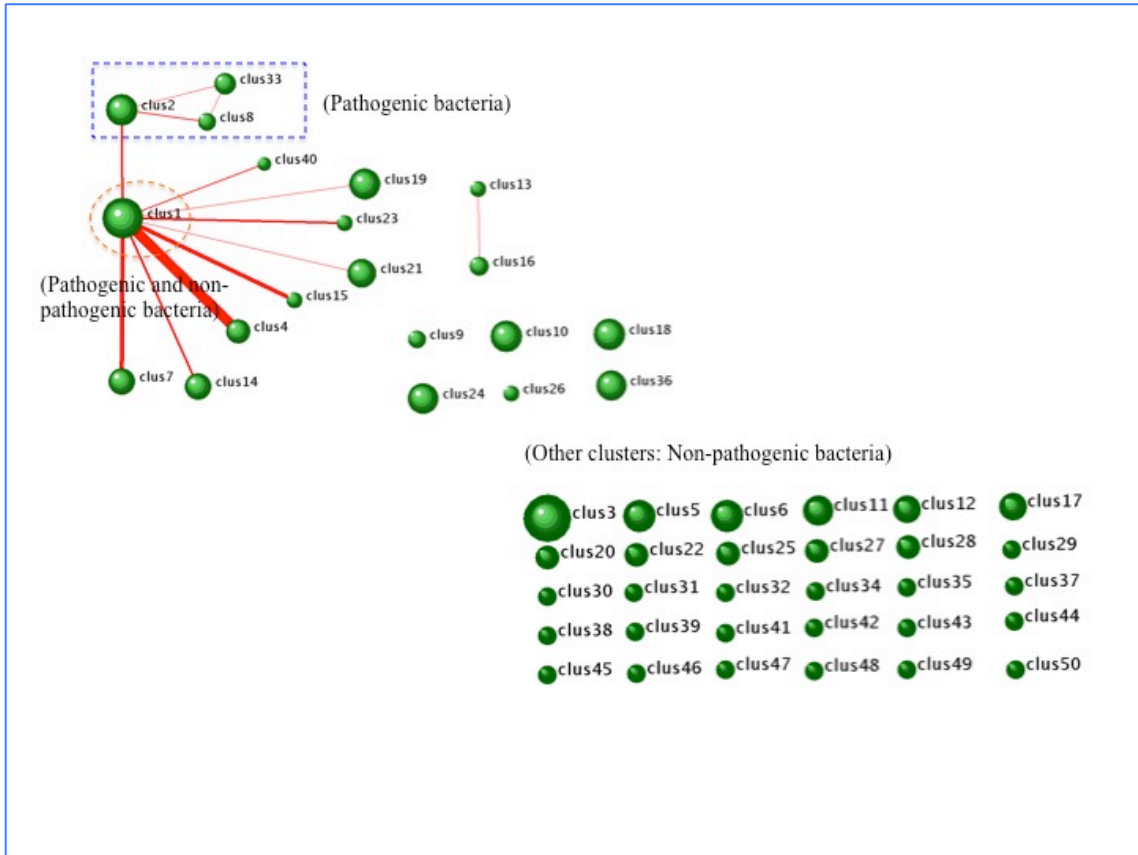

Figure 3.8. Hierarchical graph of DPCLUS clustering result in case of $cp_{in} = 0.5$ and $d_{in} = 0.9$.

3.5. Summary

The results of hierarchical clustering and graph clustering based on DPCLUS algorithm are similar in the sense that both results indicated that VOC based classification of microorganisms is consistent with their classification based on pathogenicity. However, clustering by DPCLUS further revealed existence and non-existence of relations between different pathogenic and non-pathogenic groups of microorganisms. The variation of input density value, d_{in} can affect the outcome of the clustering. It is important to choose the d_{in} value for DPCLUS clustering. The classification results between pathogenic and non-pathogenic microorganism species are best obtained in case of $cp_{in} = 0.5$ and $d_{in} = 0.6$. It is because the highest number of clusters containing pathogenic clusters (6 clusters

consisting pathogenic species) is obtained in case of $cp_{in} = 0.5$ and $d_{in} = 0.6$. The classification achieved by DPCLUS is better in a sense it produced more clusters with 100% membership of either pathogenic or non-pathogenic microorganisms.

Classification of VOCs Based On Chemical Structural Similarity

In previous chapter, we described the clustering analysis methods to cluster the microorganism species based on VOC metabolite contents similarity. In this chapter, we focus on the second type of data that we have accumulated in our database; VOCs emitted by other organisms such as plants, animals and humans with their related biological activities. For the second data, we performed heatmap clustering utilizing Tanimoto coefficient as the similarity index between chemical structures to cluster all VOCs. We further accessed the statistical significance of the clusters using hypergeometric p -values to understand the relationships between chemical structures of VOCs and their biological activities. We also compared several types of hierarchical clustering methods (single, complete, average, centroid, median linkage and Ward's method) with DPCLUS algorithm to cluster the chemical structures of VOCs using Tanimoto coefficient as a similarity measure. Additionally, we extended our analysis by implementing supervised machine learning methods such as Deep Neural Network (DNN), Gradient Boosting Machine (GBM), Random Forest (RF) and Generalized Linear Model (GLM) as classification models for predicting the biological activities of VOCs based on their chemical structures.

4.1. Background

Chemical similarity or molecular similarity refers to the similarity of chemical elements, molecules or chemical compounds with respect to either structural or functional qualities, i.e. the effect that the chemical compound has

on reaction partners in inorganic or biological settings. Biological effects and thus also similarity of effects are usually quantified using the biological activity of a compound. In pharmacology, biological activity describes the beneficial or adverse effects of a drug on living matter (Miller-Keane 1993). When a drug is a complex chemical mixture, this activity is exerted by the substance's active ingredient or pharmacophore but can be modified by the other constituents. Among the various properties of chemical compounds, biological activity plays a crucial role since it suggests uses of the compounds in the medical applications. However, chemical compounds may show some adverse and toxic effects which may prevent their use in medical practice. The notion of chemical similarity is one of the most important concepts in chemoinformatics (Nikolova & Jaworska 2003; P. 2014; Maggiora et al. 2014; Cereto-Massagué et al. 2015). It plays an important role in modern approaches to predict the properties of chemical compounds and also in conducting drug design studies by screening large databases containing structures of available chemicals.

The importance of structural similarity derives in large part from the *Similar Property Principle*, which states that molecules that are structurally similar are likely to have similar properties (Maggiora & Shanmugasundaram 2004). This relationship underlies a range of chemoinformatics techniques such as similarity searching, molecular diversity analysis, clustering and a range of quantitative structure activity relationships (QSAR) or quantitative structure–property relationships (QSPR) methods.

A similarity measure has three components: the representation or descriptor that is used to characterize the two molecules that are being compared; the weighting scheme that is used to reflect the relative importance of different parts of the representation; and the similarity coefficient that is used to quantify the degree of resemblance between two appropriately weighted structural representations. A comprehensive review by (Willett 2009) provides the detail

explanations on the three components. The book by (Todeschini & Consonni 2000; Todeschini et al. 2012; Consonni & Todeschini 2012) is the standard work on ways of describing chemical structures. Many of the descriptors reported by these authors have been used in studies of molecular similarity. They are commonly divided into three classes: whole molecule or one-dimensional (1D) descriptors; descriptors that can be calculated from two-dimensional (2D) representations of molecules; and descriptors that can be calculated from three-dimensional (3D) representations. The role of weighting schemes in similarity measures has attracted much less attention to date than have the roles of the representation and of the similarity coefficient. In a weighted fingerprint, each fragment has a weight assigned to it reflecting its relative degree of importance, so that a high-weighted fragment occurring in both the reference structure and a database structure would make a greater contribution to the overall structural similarity than would a low-weighted fragment. The most obvious form of weighting is the number of times that a fragment occurs in a molecule, so that a fingerprint encodes fragment occurrences, rather than the fragment incidences encoded in a binary fingerprint. Similarity coefficients have been developed for use in many different application domains, and there is hence a wide range available that can be used for the measurement of structural similarity. For example, a recent study by (Todeschini et al. 2012; Consonni & Todeschini 2012) discussed no less than 51 different coefficients that can be used to compute the similarity between binary fingerprints, and there have hence been many comparative studies to identify the most appropriate for chemical applications. One of the earliest such studies, (P. Willett et al. 1998) showed that the Tanimoto coefficient, an example of the class of coefficients known as association coefficients, provided an effective way of comparing 2D fingerprints. The studies conducted by (Bajusz et al. 2015) also proved that Tanimoto coefficient, along with Dice index, Cosine coefficient and Soergel distance were identified to be the best metrics for similarity calculations. This is one of the reasons why we choose Tanimoto coefficient as similarity

measure to calculate similarity between two volatile organic compounds and perform clustering.

Here, we investigate the relationships between chemical structures of VOCs and biological activities by applying unsupervised (clustering) and supervised machine learning methods (Deep Neural Network, Gradient Boosting Machine, Random Forest and Generalized Linear Model) as classification models for predicting the biological activities of VOCs based on their chemical structures.

4.2. Datasets

The second data type that we have accumulated until now are 1044 species-species interactions via 341 VOCs associated with 11 groups of biological activities. The biological activities of VOCs are classified into two types: (1) chemical ecology related activities, in which most VOCs involved in interaction between species for survival of organisms such as defense and antimicrobial, (2) human health care related activities, in which many VOCs are widely used as disease biomarker and odor. From our accumulated data, 57.3% of the activities belong to chemical ecology such as antifungal, antimicrobial, attractant, defense, enhance plant growth, inhibit root growth and repellent activities and 42.7% are human health related activities such as disease biomarker, odor, anti-cholinesterase and antioxidant as shown in Fig. 4.1. The detail explanations related to these 11 biological activities are described in Table 4.1.

Table 4.1. *The description on each of biological activities.*

Biological activities	Description on biological activities
Antifungal	Limits or prevents the growth of yeasts and other fungal organisms.
Antimicrobial	Kills or inhibits the growth of microorganisms.
Attractant	A substance, known as pheromone that attracts

	animals, such as insects.
Defense	Adaptation that promotes the survivability of an organism by protecting it from its natural enemies.
Enhance plant growth	Increase or promote plant growth.
Inhibit root growth	Decrease root growth of plants.
Repellent	A substance that deters insects or other pests from approaching or settling.
Anti-cholinesterase	An agent that inhibits acetylcholinesterase, the enzyme that breaks down acetylcholine at junctions of cholinergic nerve endings and effector organs or postsynaptic neurons.
Antioxidant	A molecule that inhibits the oxidation of other molecules.
Biomarker	A molecule, by which a particular pathological process or disease can be identified.
Odor	The property of a substance that activates the sense of smell.

There are many VOCs, which have several biological activities. Fig. 4.2 shows the relative frequencies of VOCs, which have several biological activities. There are 239 VOCs (about 70%), which have only one specific biological activity. 28 VOCs have 2 biological activities, 52 VOCs have 3 biological activities, 17 VOCs have 4 biological activities, 3 VOCs have 5 biological activities and only 2 VOCs have 6 biological activities. For simplicity, we empirically select the most relevant biological activity to each particular compound and the resultant distribution of the compounds with refer to biological activities is shown in Fig. 4.3. It facilitates to investigate the relationships between VOCs and their biological activities.

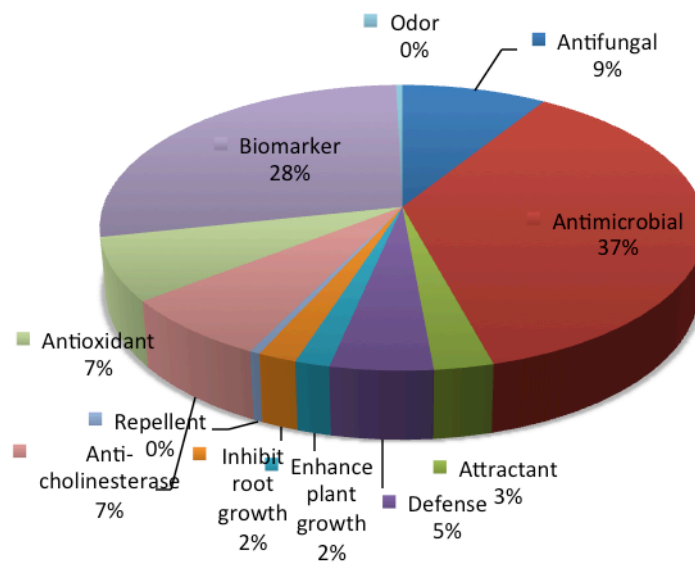

Figure 4.1. Pie chart showing the relative frequencies VOCs belonging to 11 biological activities.

Figure 4.2. The relative frequencies of VOCs, which have several biological activities.

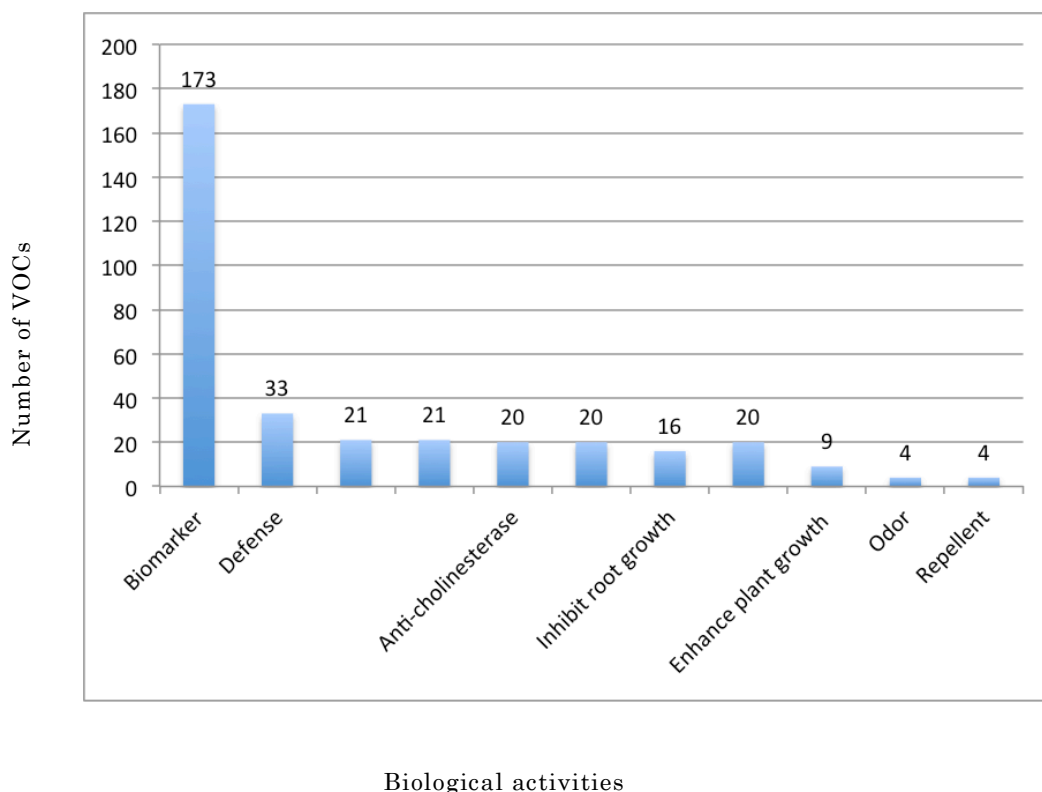

Figure 4.3. *The most relevant biological activity for each of VOCs.*

4.3. Methods

4.3.1. Heatmap clustering and hypergeometric distribution

We performed classification of VOCs based on their chemical structure similarity. In order to determine the similarity between two chemical compounds, we used Tanimoto coefficient as similarity measure. The application of Tanimoto coefficient in cheminformatics has been reported in (Butina 1999; Godden et al. 2000; Cha et al. 2009; Rojas-Cherto et al. 2012; Dimitrov et al. 2014). Recently, (Liu et al. 2013) has used Tanimoto coefficient as a novel approach to classify plants based on metabolite content similarity. The Tanimoto coefficient is defined as equation (4.1), which is the proportion of the features shared between two

compounds divided by their union (Peter Willett et al. 1998).

$$Tanimoto_{A,B} = \frac{AB}{A+B-AB} \quad (4.1)$$

The variable AB is the number of features (or on-bits in binary fingerprint) common in both compounds, while A and B are the number of features that are related to individual compounds respectively. The Tanimoto coefficient has a range from 0 to 1 with higher values indicating greater similarity than lower ones. Additionally, a Tanimoto coefficient value larger than 0.85 indicates that the compared compounds may have similar biological activity (Patterson et al. 1996). For the purpose of calculating Tanimoto coefficient, it is obligatory to assign fingerprints to the compounds. ChemMine package in R was used to generate binary fingerprints and calculation of Tanimoto coefficient (Cao et al. 2008; Cao et al. 2014). 2-D compound structures in the generic structure definition file (SDF) format were obtained from PubChem database (<https://pubchem.ncbi.nlm.nih.gov>) and then, were imported into ChemmineR package in one batch file. The binary PubChem fingerprints are calculated during the SDF import and stored in a searchable descriptor database as a list object. The detail description of PubChem fingerprint can be referred in Appendix A.

Based on Tanimoto similarity measure between chemical structures, heatmap clustering was performed for classifying the VOCs. We also determined the p -values of the clusters based on hypergeometric distribution using equation (4.2).

$$p - value = 1 - \sum_{i=0}^{K-1} \frac{\binom{V}{i} \binom{N-V}{C-i}}{\binom{N}{C}} \quad (4.2)$$

Here N is the total number of VOCs, C is the size of a cluster and V and K respectively are the number of VOCs of a certain category in the whole data and in the cluster. The hypergeometric distribution is used to calculate the statistical significance of having drawn a specific K successes (out of N total draws) from the whole population. The test is often used to identify which sub-populations are over- or under-represented in a sample. The calculated p -value implies the probability of getting K or more VOCs of a particular category in a cluster when the cluster is formed by random selection. Lower p -value indicates that the statistical significance is high.

Our purpose is to relate a structure group to a biological activity if and only if the structure group is overrepresented by VOCs associated with that biological activity.

4.3.2. Comparison of clustering methods

Based on Tanimoto similarity measure, we applied two different clustering methods to classify the VOCs, which are DPCLUS clustering and hierarchical clustering. Both methods were described in Chapter 3. The reason why we apply both methods is that, we want to determine the degree of cluster overlap and how well it classified chemical structures of VOCs into clusters. Additionally, we also point out the advantages and limitations of both clustering methods.

A network of VOCs was constructed by selecting structurally highly similar VOC pairs for applying the DPCLUS algorithm. In DPCLUS, a network is considered as an undirected simple graph $G = (N, E)$ that consists of node set N and edge set E . Density d_k of any cluster k is the ratio of the number of edges present in the cluster ($|E|$) and the maximum possible number of edges in the cluster ($|E|_{max}$). The cluster property of node n with respect to cluster k is represented by $cp_{nk} = E_{nk} / (d_k \times N_k)$, where N_k is the number of nodes in cluster k . E_{nk} is the total

number of edges between the node n and each of the nodes of cluster k .

Meanwhile, hierarchical clustering involves creating clusters that have a predetermined ordering from top to bottom, or otherwise. Before any clustering is performed, it is required to determine the proximity matrix containing the distance between each point using a distance function. Then, the matrix is updated to display the distance between each cluster. In this study, we use 6 different methods depending on how the distance between each cluster is measured that is single, complete, average, centroid, median and Ward's method.

4.3.3. Molecular fingerprints

To extend our findings, we also developed classification models to predict biological activities of VOCs based on their chemical structures by several machine learning methods such as Deep Neural Network (LeCun et al. 2015; Ma et al. 2015; Chandra & Sharma 2016), Gradient Boosting Machine (Friedman 2001; Friedman 2002; Natekin & Knoll 2013; Chen & Guestrin 2016), Random Forest (Breiman 2001) and Generalized Linear Model (Cook 1998). Eight types of molecular fingerprints are used to represent the molecules, as following:

- (1) PubChem (PubChem, 881 bits),
- (2) CDK (CDK, 1024 bits),
- (3) Extended CDK (Extended, 1024bits),
- (4) MACCS (MACCS, 166 bits),
- (5) Klekota-Roth (KR, 4860 bits) (Klekota & Roth 2008),
- (6) Substructure (SubFP, 307 bits),
- (7) Estate (Estate, 79 bits),
- (8) Atom pairs (AP, 780 bits) (Carhart et al. 1985).

The detail description on substructures and each fingerprint method can be referred to this website (<http://www.scbdd.com/chemdes/list-fingerprints/>). We also proposed a new type of fingerprint, by combining all features and substructures obtained by these fingerprints (Combine, 9121 bits). The reason why we use many types of fingerprints, is that we want to investigate which fingerprint method can generate the best prediction model. We converted the SDF files of all 341 VOCs into binary fingerprints using ChemDes software (Dong et al. 2015). After we obtained the binary matrix of fingerprints, we performed the data-processing method by removing all columns that contain “0”. This is because it might be not relevant for the classification of VOCs based on substructures. The features or substructures displayed in binary matrix, was used as input to the classification models. There are 11 classes of biological activities, which have been used as outputs for the classification model. The VOC-Substructure-Biological activities relations can be represented as a matrix, shown in Table 4.2 where rows represent VOCs and columns represent substructures of molecular fingerprints. We added one additional column to represent biological activities for each of VOCs.

Table 4.2. *Representation of VOCs, substructures and biological activities as a two-dimensional matrix.*

VOCs	Substructures						Biological
	S ₁	S ₂	S ₃	S ₄	...	S _M	Activities
VOC ₁	1	0	1	1	...	0	Antimicrobial
VOC ₂	1	1	0	0	...	0	Biomarker
VOC ₃	0	1	0	1	...	0	Defense
...	
VOC _N	1	0	0	0	...	1	Odor

Machine learning algorithms are generally developed in computer science or adjacent disciplines and find their way into chemical modeling by a process of diffusion. Recently, machine learning methods are popular in chemoinformatics and quantitative structure–activity relationships (QSAR), which usually predicting the unknown property values of a test set of molecules based on the known values for a training set. An example of existing machine learning algorithms is given in Fig. 4.4. We implemented four types of supervised machine learning methods for predicting biological activities of VOCs, which are Deep Neural Network (DNN), Gradient Boosting Machine (GBM), Random Forest (RF) and Generalized Linear Model (GLM) using H2O package in R program (Intelligence 2015; Anqi et al. 2015).

Figure 4.4. Example of existing machine learning algorithms.

4.3.4. Deep Neural Network (DNN)

A neural network is network composed of simulated “neurons”. Each neuron has multiple inputs and one output. Each input arrow is associated with a weight, w_i . The neuron is also associated with a function, $f(z)$, called the activation function, and a default bias term b , as shown in Fig. 4.5.

Figure 4.5. *The basic unit of a neuron.*

A row of neurons form a layer of the neural network, and a DNN is built from several layers of neurons (Fig. 4.6).

Figure 4.6. *The deep neural network model.*

Normally, there are three types of layers in a DNN: (1) the input layer, where the fingerprint of a molecule is entered (2) the output layer where predictions are generated (3) the hidden (middle) layers; the word “deep” in deep neural nets implies more than one hidden layer. In this study, we used 3 types of activation functions in the hidden layers: (1) the tanh function, (2) the rectified linear unit (ReLU) function (Maas et al. 2013), and (3) the maxout function (Goodfellow et al. 2013; Zhang et al. 2014). The output layer can have one or more neurons, and each output neuron generates prediction for biological activities. The layout of a DNN, including the number of layers and the number of neurons in each layer, needs to be defined, along with the choice of the activation function in each neuron. Dropout is a method, which remove some of neurons in the input and hidden layer to avoid over fitting (Srivastava et al. 2014; Baldi & Sadowski 2014). Since there are a lot of parameters that can impact model accuracy, we implemented hyper-parameter tuning for the network optimization. Multi-dimensional hyper-parameter optimization (more than 4 parameters) can be more efficient with random parameter search. For a random parameter search, we did a loop over models with parameters drawn uniformly from a given range, and then we chose the best parameter for our DNN network.

4.3.5. Gradient boosting machine (GBM)

Gradient boosting machines are a family of powerful machine-learning techniques for regression and classification problems, which produces a prediction model in the form of an ensemble of weak prediction models, typically decision trees (Natekin & Knoll 2013). It builds the model in a stage-wise fashion like other boosting methods do, and it generalizes them by allowing optimization of an arbitrary differentiable loss function. Gradient boosting involve three elements; (1) A loss function to be optimized, (2) A weak learner to make predictions and (3)

An additive model to add weak learners to minimize the loss function. It is clear that these elements would greatly affect the GBM model properties. The GBM framework provides the practitioner with such design flexibility.

4.3.6. Random forest (RF)

RF is an ensemble method that consists of many decision trees (Breiman 2001) for classification and regression tasks. It operates by constructing a multitude of decision trees at training time and outputting the class that is the mode of the classes output by individual trees. For prediction a new sample is pushed down the tree. It is assigned the label of the training sample in the terminal node it ends up in. This procedure is iterated over all trees in the ensemble and the mode vote of all trees is reported as the random forest prediction.

4.3.7. Generalized linear model (GLM)

In statistics, the generalized linear model (GLM) is a flexible generalization of ordinary linear regression that allows for response variables that have error distribution models other than a normal distribution. The GLM generalizes linear regression by allowing the linear model to be related to the response variable via a link function and by allowing the magnitude of the variance of each measurement to be a function of its predicted value. Generalized linear models were formulated by (Nelder & Wedderburn 1972) as a way of unifying various other statistical models, including linear regression, logistic regression and Poisson regression. They proposed an iteratively reweighted least squares method for maximum likelihood estimation of the model parameters. Maximum-likelihood estimation remains popular and is the default method on many statistical computing packages. Other approaches, including Bayesian approaches and least squares fits

to variance stabilized responses, have been developed.

4.3.8. Evaluation of model performance

The performance of multi-classification models were measured by mean squared error (MSE) value. We conducted two experiments; (1) Using all datasets as training, (2) Using 10-fold cross-validation technique. In this technique, the compounds were randomly divided into ten parts, where nine parts were used for training and remaining part for testing. This process is carried out ten times in such a way that each part was used once for testing.

4.4. Results and discussion

4.4.1. Heatmap clustering and hypergeometric distribution

Initially, we determined pairwise chemical structural similarity between VOCs based on Tanimoto coefficient. 2-D compound structures in the generic structure definition file (SDF) format of all 341 VOCs were obtained from PubChem database (<https://pubchem.ncbi.nlm.nih.gov>) and then, were imported into ChemmineR package (Cao et al. 2014) in one batch file. We calculated the chemical structure similarity using Tanimoto coefficient. Then, we converted the Tanimoto similarity matrix into distance matrix by subtracting each of the similarity values from 1. Based on distance matrix, we performed heatmap clustering and the result is shown in Fig. 4.7. White and red colors indicate the extreme distance values of 0 and 1 respectively and the intermediate distance values are indicated by the intensity of the red color. From the heatmap plot, we tentatively outlined 11 clusters of VOCs. The count of VOCs belonging to each activity group in each cluster is shown in Table 4.3. To assess the richness of VOCs of similar activity in individual clusters, we determined their p -values based on hypergeometric distribution which are also shown in Table 4.3. The major types of chemical compounds belonging to each cluster and their

corresponding biological activities are mentioned in Table 4.4. The chemical structures of the VOCs belonging to all clusters (Cluster 1 to Cluster 11) are shown in Appendix B.

Figure 4.7. Heatmap clustering of VOCs based on chemical structure similarity determined by Tanimoto coefficient.

Table 4.4. *Summary of clustering result and its descriptions related to chemical structures and biological activities.*

Cluster ID (Count)	Description on chemical structures	Related biological activities
Cluster 1 (55 VOCs)	All compounds are terpenoids. 15 VOCs are monoterpenoids (10 carbon) and 40 VOCs are sesquiterpenoids (15 carbon).	Anti-cholinesterase, antimicrobial, antioxidant, defense.
Cluster 2 (33 VOCs)	17 VOCs are alcohol, aldehyde, ketone, epoxide and ester of terpenoids. The other VOCs are alcohol, aldehyde, carboxylic acid, ester and ketone of straight-chain alkenes.	Anti-cholinesterase, antimicrobial, antioxidant.
Cluster 3 (41 VOCs)	Alkanes.	Biomarker.
Cluster 4 (18 VOCs)	Alkenes.	Antifungal.
Cluster 5 (21 VOCs)	Aldehyde, ester, carboxylic acid and ketone of C8-C18 alkanes.	Anti-cholinesterase, antimicrobial, antioxidant, biomarker, repellent.
Cluster 6 (25 VOCs)	21 VOCs are alcohol and ether of C3-C8 alkanes.	Enhance plant growth, inhibit root growth, odor.
Cluster 7 (47 VOCs)	45 VOCs are ester, carboxylic acid, ketone and aldehyde of non-cyclic C2-C9 alkanes.	Attractant, biomarker.
Cluster 8 (15 VOCs)	VOCs consist of epoxide, ethers, esters and alcohols.	-
Cluster 9 (42 VOCs)	24 VOCs are aromatic alcohols, carboxylic acids, esters, ketones, and ethers. 16 VOCs are aromatic compounds consisting of C and H atoms. One VOC consists of C, H and Br atoms. One VOC is an alkane ester.	Attractant.
Cluster 10 (14 VOCs)	Aromatic compounds. 12 VOCs are hetero-aromatic compounds that consist of one or more sulfur, nitrogen or oxygen atoms.	Biomarker.
Cluster 11 (30 VOCs)	VOCs are quite diverse in chemical elements, C0-C6 small molecules.	Biomarker.

From this result, we can see that there are 55 VOCs belong to Cluster 1 and mainly involved with anti-cholinesterase, antimicrobial, antioxidant and defense activities, for example beta-caryophyllene, isocaryophyllene and caryophyllene. All compounds in Cluster 1 are terpenoids, of which 15 VOCs are monoterpenoids (10 carbon units) and 40 VOCs are sesquiterpenoids (15 carbon units). There are 33 VOCs in Cluster 2 and the *p*-values corresponding to anti-cholinesterase, antimicrobial and antioxidant are 4.849×10^{-4} , 9.696×10^{-4} and 4.849×10^{-4} respectively. Some of the VOCs that are classified into Cluster 2 are monoterpenoids and sesquiterpenoids such as beta-linalool, terpinen-4-ol, p-menth-1-en-8-ol, drimenol and nerolidol. 17 VOCs are alcohol, aldehyde, ketone, epoxide and ester of terpenoids. The other VOCs are alcohol, aldehyde, carboxylic acid, ester and ketone of straight-chain alkenes.

For Cluster 3, there are 41 compounds and the main biological activities involved is biomarker for various diseases such as colorectal cancer and asthma. We obtained small *p*-value (1.835×10^{-3}) for biomarker activity of Cluster 3. All compounds are alkanes, of which most of them are emitted in human breath such as octane, isobutane, 2-methylpentane, methylcyclohexane, hexane and cyclohexane.

There are 18 compounds in Cluster 4 and all of them are alkenes such as beta-farnesene, alpha-caryophyllene, ocimene and beta-ocimene. These compounds are mainly associated with chemical ecology activity, which is antifungal and the *p*-value for this activity is 2.561×10^{-2} . For Cluster 5, there are 21 VOCs which are aldehyde, ester, carboxylic acid and ketone of C8-C18 alkanes. Cluster 5 is significantly related with multiple biological activities, that are anti-cholinesterase, antimicrobial, antioxidant, biomarker and repellent activities. There are 25 VOCs in Cluster 6 and 21 of them are alcohol and ether of C3-C8 alkanes. We also obtained small *p*-value for enhance plant growth activity (3.531×10^{-3}), inhibit root growth (4.111×10^{-2}) and odor activity (2.29×10^{-5}) for

cluster 6. An example of VOCs involved in enhance plant growth activity is 2,3-Butanediol and there are many reports that this compound released by soil microorganisms had improved plant growth and increased pathogen resistance (Ryu et al. 2003; D'Alessandro et al. 2014). For odor activity, compounds involved are in alcohol sulfanylalkanols chemical class group such as 2-methyl-3-sulfanylbutan-1-ol and 3-methyl-3-sulfanylhexas-1-ol. These compounds have a pungent sweat odor, also reminiscent of onions with some fruity connotations which are transformed into the volatile substances by bacterial enzymes present only in corynebacteria.

There are 47 VOCs in Cluster 7 and 45 of them are ester, carboxylic acid, ketone and aldehyde of non-cyclic C2-C9 alkanes. Cluster 7 is significantly related with multiple biological activities, which are attractant (p -value = 3.829×10^{-2}) and biomarker for various diseases (p -value = 4.42×10^{-5}). Aldehydes belong to Cluster 7 such as acetaldehyde, propanal, hexanal, 2-methyl-butanal, pentanal, heptanal and 3-methyl-butanal are mostly used as a biomarker for various diseases including cancer and irritable bowel syndrome. In Cluster 8, there are 15 VOCs belong to this cluster, which consist of epoxide, ethers, esters and alcohols. In Cluster 9, there are 42 VOCs and the main biological activity is attractant (p -value = 1.983×10^{-2}). All VOCs belong to Cluster 9 are aromatic compounds, in which 24 VOCs are aromatic alcohols, carboxylic acids, esters, ketones and ethers. 16 VOCs are aromatic compounds consisting of C and H atoms. One VOC consists of C, H and Br atoms. One VOC is an alkane ester. Also, there are 14 VOCs in Cluster 10 which are aromatic compounds. 12 VOCs are hetero-aromatic compounds that consist of one or more sulfur, nitrogen or oxygen atoms. In Cluster 11, which consists of 30 VOCs, but their VOCs are quite diverse in chemical elements and have C0-C6 small molecules, ranging from hydrogen cyanide (27.02534 g/mol) to tetrachloroethylene (165.8334 g/mol). The main biological activity for Cluster 10 and Cluster 11 are biomarker for various

diseases. The p -values for biomarker activity for Cluster 10 and Cluster 11 are 1.036×10^{-2} and 1.963×10^{-3} , respectively. The major VOCs involved in this activity are isoxazole, 2,3-dimethyl-pyrazine, and 2-methyl-pyrazine which are mostly produced in human urine and can be used as biomarker for autism spectrum disorders (Cozzolino et al. 2014; Dieme et al. 2015).

The heatmap clustering shows that there are strong links between chemical structure of VOCs and their biological activities. Comparative activity relationships between chemical ecology and human health care activity will lead to systematization of metabolomics combined with human and ecological metabolic pathways.

4.4.2. Comparison of clustering methods

To extend our studies, we compared two different clustering methods (DPCLUS and hierarchical clustering) to cluster all 341 VOCs that we accumulated in our database. In case of DPCLUS algorithm, we used 0.6 as input density d_{in} and 0.5 as input cluster property cp_{in} . DPCLUS generated 56 clusters. Figure 4.8 (a) shows the interacted clusters while Fig. 4.8 (b) shows the independent clusters of DPCLUS.

(a)

(b)

Figure 4.8. (a) *Interacted clusters of DPCLUS.* (b) *Independent clusters of DPCLUS.*

To be consistent, we extracted 50 clusters based on hierarchical clustering. The size of the biggest cluster generated by DPCLUS is 18 while in case of hierarchical clustering it is 98 (centroid's method) as shown in Fig. 4.9. It is also observed that in hierarchical clustering, there is some imbalance in the size of generated clusters. On the other hand, the clusters generated by DPCLUS algorithm are in balanced size (Abdullah et al. 2016).

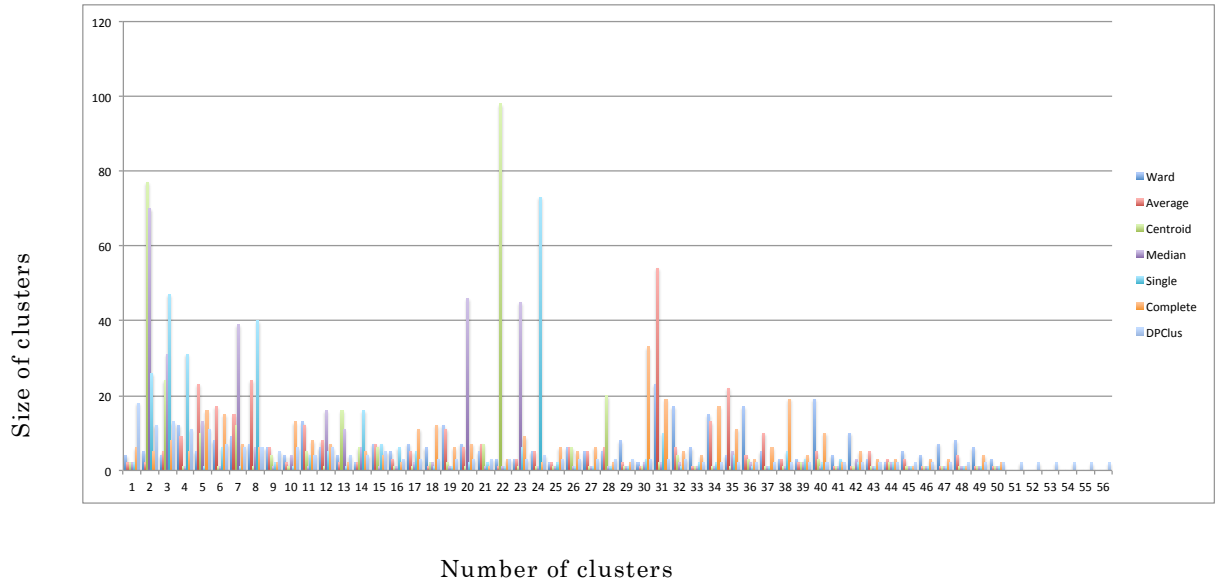

Figure 4.9. Distribution of cluster with refer to size generated by DPCLUS and each linkage method of hierarchical clustering.

For comparison purpose, we also investigated how the generated clusters by these two clustering methods match to each other. To calculate how effectively DPCLUS generated clusters overlaps with hierarchical clusters, we use a matching score measure, m as follow:

$$m = \frac{i^2}{a \times b}$$

Here, a is the size of a cluster generated by DPCLUS, b is the size of a clusters generated by hierarchical method and i is the size of the intersection set of a and b . The calculated matching score is ranged between 0 and 1, where value of 1 shows the maximum overlapping score between two generated clusters. The distribution of matching score between DPCLUS and each method of hierarchical clustering is shown as Fig. 4.10.

Figure 4.10. *Distribution of clusters with refer to matching score for DPCLUS and each linkage method of hierarchical clustering.*

From this figure, we can observe that the Ward's method of hierarchical clustering has the most matching clusters with DPCLUS algorithm while median has the least matching clusters with DPCLUS. Both DPCLUS and hierarchical methods generated clusters of VOCs with high structural similarity and similar biological activity. For example, cluster 1 generated by DPCLUS algorithm contains 18 VOCs, which are terpenoids and their biological activities are anti-cholinesterase, antimicrobial and defense activities. These results somehow aligned with our previous results, where we have shown that structurally similar group of VOCs generated by hierarchical clustering correspond to similar biological functions by conducting statistical analysis involving hypergeometric distribution based p -values (Abdullah et al. 2015).

Another comparison measure is Rand index. The Rand index or Rand measure, is a measure of the similarity between two data clustering methods (Rand 1971). It is calculated by using the following equation,

$$Rand = \frac{a + d}{a + b + c + d}$$

where a is number of point pairs in the same cluster A and B , b is number of point pairs in the same cluster A not B , c is number of point pairs in the same cluster B not A and d is number of point pairs in different cluster A and B . Table 4.5 shows the Rand index value for the comparison between DPCLUS and each hierarchical clustering methods. From this table, we can see that the Complete method has high similarity with Ward and Average method. DPCLUS has high similarity with Average and Ward's method, but has low similarity with Median method. This result somehow is aligned with the result displayed in Fig. 4.10, where we have shown that DPCLUS has lowest similarity with Median method. It seems that DPCLUS clustering is quite different from each of hierarchical clustering method. This is because the different nature of the clustering algorithm itself. Hierarchical clustering builds models based on distance connectivity while DPCLUS is a graph clustering method, based on a subset of nodes in a graph such that every two nodes in the subset are connected by an edge which can be considered as a prototypical form of clustering.

Table 4.5. *Rand index value for comparison between two clustering methods.*

	Ward	Average	Centroid	Median	Single	Complete	DPCLUS
Ward							
Average	0.875						
Centroid	0.717	0.729					
Median	0.714	0.707	0.710				
Single	0.788	0.793	0.666	0.704			
Complete	0.883	0.884	0.718	0.727	0.799		
DPCLUS	0.701	0.723	0.650	0.642	0.675	0.718	

In this section, we discussed two different clustering methods, namely DPCLUS graph clustering and hierarchical clustering to cluster the chemical structures of volatile organic compounds (VOCs) using Tanimoto coefficient as chemical similarity measure. Additionally, we compared the performances of DPCLUS algorithm with 6 different methods of hierarchical clustering, which are single, complete, average, centroid, median and Ward's method. Based on matching score, we found that Ward's method has the most matching clusters with DPCLUS while median has the least matching clusters. Using Rand index, we found that Complete method has similarity with Average and Ward's method. Compared to hierarchical clustering, DPCLUS can give a better visualization of how generated clusters are interacted with each other and we found that VOCs belonging to the interacted clusters have similar chemical structure, which indicates possibilities of exhibiting similar biological activities. In conclusion, chemical similarity measure can be used to predict biological activities of a compound and this can be applied in the medical and agrotechnology fields.

4.4.3. Supervised machine-learning methods

In previous section, we compared the performance of two clustering methods; DPCLUS graph clustering and hierarchical clustering to classify volatile organic compounds (VOCs) using fingerprint-based similarity measure between chemical structures. Using the same datasets as mentioned earlier, we extended the studies by implementing supervised machine learning methods to classify the VOCs based on chemical structures. The main difference between unsupervised (clustering) method and supervised machine learning is that, supervised machine learning methods need an output class variable. In supervised learning, each example is a pair consisting of an input object and a desired output.

In this study, we have developed 72 classification models to predict biological activities of VOCs by four types of supervised machine-learning methods, which are DNN, GBM, RF and GLM. Eight types of molecular fingerprints are used to represent the molecules, which are PubChem (PubChem, 881 bits), CDK (CDK, 1024 bits), Extended CDK (Extended, 1024bits), MACCS (MACCS, 166 bits), Klekota-Roth (KR, 4860 bits), Substructure (Sub, 307 bits), Estate (Estate, 79 bits) and atom pairs (AP, 780 bits). We also proposed a new type of fingerprint, called Combine (Combine, 9121 bits) by combining all features or substructures obtained by these eight fingerprints. After removing all "0" columns from the binary matrix, we input as classification models to the machine learning methods for prediction of biological activities.

It is difficult and time-consuming to find the best parameters for DNN due to the large number of adjustable parameters. Hence we took the approach by choosing the best parameter by using the multi-dimensional hyper-parameter optimization method. We selected the best parameter and then, compared with the default parameter. Table 4.6 shows the DNN parameter used in this study.

Table 4.6. *List of DNN parameters used in this study.*

Parameter list	DNN 1 (default)	DNN 2	DNN 3	DNN 4	DNN 5
Activation function	Rectifier	Tanh	Maxout	Rectifier with Dropout	Maxout
Input dropout ratio				20%	
Hidden dropout ratio				20%, 20%, 20%, 20%, 20%	
Hidden layer 1	200	200	200	200	200
Hidden layer 2	200	200	200	200	200
Hidden layer 3				200	200
Hidden layer 4				200	200
Hidden layer 5				200	200
Epoch	10	10	10	10000	10000

We used the default setting for DNN 1; Rectifier activation function, 200 neurons in both hidden layer 1 and hidden layer 2 and epochs was set to 10. We varied the parameter for DNN 2 and DNN 3 by using the Tanh and Maxout activation function. For DNN 4, we selected the best parameter based on multi-dimensional hyper-parameter optimization method; Rectifier activation function with dropout, 5 hidden layers, 200 neurons in every hidden layer, 20% dropout rate in input layer and each of hidden layer and the epoch was set to 10000. For DNN 5, we used the Maxout activation function, 5 hidden layers, 200 neurons in every hidden layer and the epoch was set to 10000. Other than DNN, we also compared the classification performance of GBM, RF and GLM methods. Table 4.7 shows the list of classification models using different fingerprints and machine learning methods.

We conducted two types of experiments; (1) Using all datasets as training and (2) Using 10-fold cross validation technique. A full list of classification results for both experiments (in terms of MSE value and accuracy) is available in the Appendix C.

For the first experiment, by using all datasets as training, the best classification model was developed by Klekota-Roth fingerprint trained with Deep Neural Network 4 (DNN 4) method, with MSE value 0.05420784. Second best classification model was developed by PubChem fingerprint with MSE value 0.05871162, followed by MACCS fingerprint with MSE value 0.07807859. Both fingerprints were also trained with Deep Neural Network 4 (DNN 4). The best parameter for deep learning was obtained by using rectifier activation function with dropout rate at 20%. Number of hidden layer was set to 5 and 200 neurons for each of hidden layer. Estate and atom pair fingerprint did not perform well in the classification model. This is because the length of the Estate fingerprint is only 79 bits, which is too short to characterize molecules. Too much information loss led to the bad prediction.

For the second experiment, we adopted the 10-fold cross-validation technique

to evaluate the performance of our models. The lowest MSE error was obtained by using PubChem fingerprint trained by GBM method at 0.39318013, followed by Combine fingerprint also trained by GBM method. The obtained MSE error was 0.39837325. MACCS fingerprint trained by GBM method also gave good MSE value at 0.39979038 compared to other models. The worst performance was obtained using Extended fingerprints trained with Deep Neural Network 4 (DNN 4) and Estate fingerprint trained with Deep Neural Network 3 (DNN 3).

Fig. 4.11 shows the performance of 72 classification models (MSE value) by using all datasets as training and 10-fold cross validation technique. It seems that all data are distributed randomly and there is no correlation between the performance obtained by using all datasets as training and 10-fold cross validation technique.

1

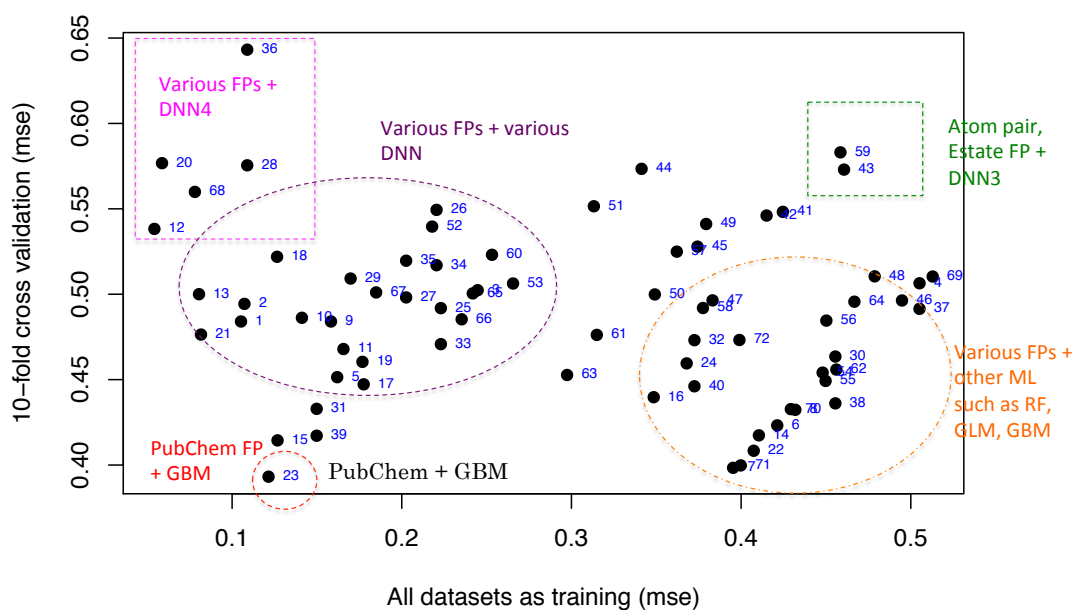

Figure 4.11. Performance of 72 classification models by using all datasets as training and 10-fold cross validation technique (MSE value).

We observed that there are two types of models: 1) the left side is affected by over-fitting problem, and 2) the right side is not changed for both experiments. The left side points, which most of the combination of fingerprint types and DNN methods suffered from over-fitting problems due to the many parameters of DNN. The performance of DNN is good when using all datasets as training, however it becomes worst when we used 10-fold cross validation technique, such as model No 12 (Klekota-Roth fingerprint trained with DNN4 method) and model No 36 (Extended fingerprint trained with DNN4 method). This might be caused by the small number of our sample data and many parameters of DNN. DNN always requires a large amount of data to be trained, usually more than 50,000 samples. In our study, we only have 341 VOC data for the classification task. In theory, over-fitting is a major problem for DNN and we have proved this experimentally. Moreover, the Klekota-Roth and Extended fingerprints have many substructures or features (more than 1000), which need to be trained and as a result, they are suffering from over-fitting problems. The right side points did not change much for both experiments. For example, the classification model No 43 (atom pair fingerprint trained with DNN3 method) and model No 59 (Estate fingerprint trained with DNN3 method) performed poorly in both experiments. From this result, we can understand two things; 1) Atom pair and Estate fingerprint did not perform well in model building, 2) DNN3 is the worst, compared to other DNN models. Atom pair fingerprint are a structural descriptor type that is defined by the shortest paths among the non-hydrogen atoms in a molecule. Each path is described by the types of atoms in a pair, the length of their shortest bond path, the number of their pi electrons and the non-hydrogen atoms bonded to them. The number of atom pairs describing a molecule grows with its number of atoms. The fingerprints provided by PubChem are a binary representation of the presence and absence of a library of 881 substructure features. Compared to atom pairs, the PubChem fingerprints are a knowledge-based system that stores less information than the much more complex and unbiased atom pair concept. PubChem fingerprints are also less sensitive than atom pair descriptors. The length of the Estate fingerprint is only 79 bits, which is too short to characterize molecules and some of the information might be loss, which cause the bad prediction. It is also observed that hyper parameters of DNN can affect the overall performance. The

reason why DNN3 performed poorly for both experiments, is because the Maxout activation function and a small number of epochs. Rectifier activation function is a better choice for this classification task.

Based on Fig. 4.10, we can observe that the classification model No 23 (PubChem fingerprint trained with GBM method) gives good results in both experiments. This model obtained MSE value = 0.1214795 when using all datasets as training and MSE value = 0.39318013 in case of 10-fold cross validation technique. The results show that GBM method is good at predicting biological activities of VOCs. GBM appears to be a very effective and efficient machine-learning method. It is efficient because it achieves these results with much less computational effort than either of those methods and produces much smaller models. This is also supported by (Sheridan et al. 2016), where they compared eXtreme Gradient Boosting (XGBoost) to random forest and single-task deep neural nets on 30 in-house data sets and found that XGBoost can make prediction better than those of random forest and almost as good as those of deep neural nets. Overall, GBM results somehow are contrary with DNN results.

We also evaluated the performance of all 72 models in term of classification accuracy. Classification accuracy is the ratio of correct predictions to total predictions made and often presented as a percentage by multiplying the result by 100. Fig. 4.12 shows the performance of 72 classification models in term of accuracy value (%) by using all datasets as training and 10-fold cross validation technique. Also, it can be seen that all data are distributed randomly and there is no correlation between the performance obtained by using all datasets as training and 10-fold cross validation technique. Similarly to MSE result, we observed that there are two types of models: 1) the right side is affected by over-fitting problem, and 2) the left side is not changed for both experiments. The right side models, such as model No 12 (Klekota-Roth fingerprint trained with DNN4 method), model No 20 (PubChem fingerprint trained with DNN4 method) and model No 36 (Extended fingerprint trained with DNN4 method) give good classification result when using all datasets as training, however it becomes worst when we used 10-fold cross validation technique. This might be caused by the small number of our sample data, many parameters of DNN and large number of features need to be trained, which we have explained previously.

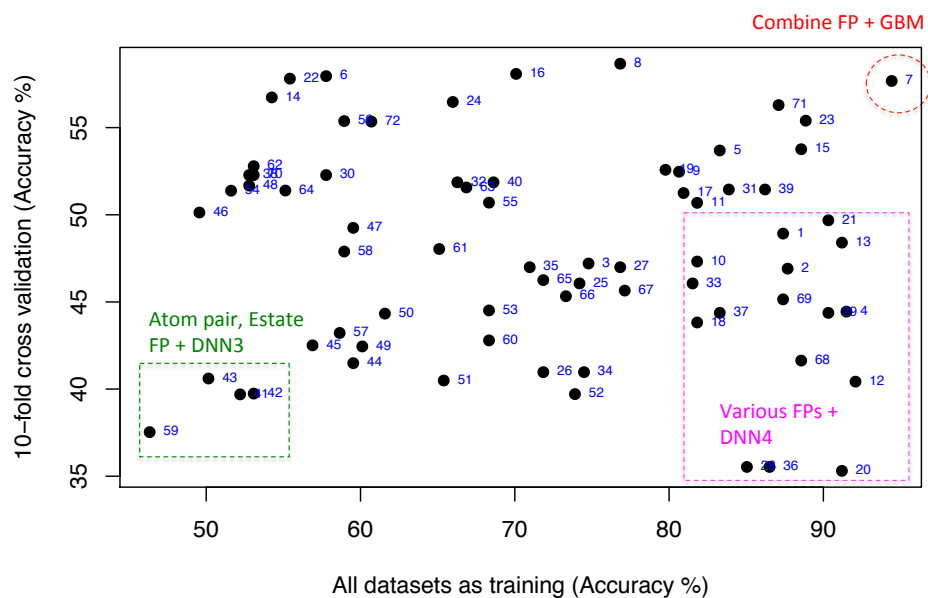

Figure 4.12. Performance of 72 classification models by using all datasets as training and 10-fold cross validation technique (accuracy).

Contrarily, there are few models which performed poorly in both experiments. The classification model No 43 (atom pair fingerprint trained with DNN3 method) and model No 59 (Estate fingerprint trained with DNN3 method) performed poorly in case of using all datasets as training and 10-fold cross validation technique. This is due to the small number of substructures for Estate fingerprint, which is too short to characterize molecules. The atom pair fingerprint is also known as a very sensitive fingerprint and this is the reason why it performed poorly in both experiments. Based on Fig. 4.11, we observed that the classification model No 7 (Combine fingerprint trained with GBM method) gives good results in both experiments. This model obtained accuracy value of 94.4% when using all datasets as training and 57.7% in case of 10-fold cross validation technique. The results

show that GBM method is good at predicting biological activities of VOCs. This result somehow is aligned with our previous result shown in Fig. 4.10, where we proved that GBM appears to be a very effective and efficient algorithm, compared to other machine learning methods.

4.4.4. Identification of important substructures

In the Section 4.4.3, we explained the performance of DNN, GBM, RF and GLM machine learning methods to predict the biological activities of VOCs based on chemical structures. The best classification model was built by using GBM algorithm along with PubChem fingerprint. Hence, we identified the important substructures for PubChem fingerprint using GBM algorithm for the purpose of predicting biological activities. The H2O R package has implemented the method of Gedeon (Gedeon 1997) in order to find the variable importance in descending order of importance. GBM algorithm can automatically calculate variable importance, which include the absolute and relative predictive strength of each feature in the prediction task. The most important substructures (top 5) during classification were PubChemFP430, PubChemFP2, PubChemFP334, PubChemFP14 and PubChemFP839. The detail description for each of the substructures are given below (refer to Appendix A for detail).

- 1) PubchemFP430: C(-C)(-C)(=C)
- 2) PubchemFP2: >= 16 H
- 3) PubchemFP334: C(~C)(~C)(~C)(~C)
- 4) PubchemFP14: >= 1 N
- 5) PubchemFP839: CC1CC(C)CC1

It was observed that PubChem fingerprint number 430 ranked the highest in the context of classifying biological activities of VOCs. This fingerprint

represents the detailed atom neighborhood. The second highest rank was PubChem fingerprint number 2, which represents the presence of 16 hydrogen atoms in a compound. Based on the frequency of these substructures presence in each of VOC, we identified the most relevant biological activity for each compound. For example, PubChem fingerprint number 430 has contributed most to the attractant and biomarker activities. Most of VOCs, which have attractant and biomarker activities consist only this particular fingerprint. PubChem fingerprint number 2, which represents the presence of 16 hydrogen atoms contribute to chemical ecology activities such as repellent, antimicrobial, antifungal and defense. PubChem fingerprint number 334 has occurred in most of VOCs, which have human healthcare activities such as anti-cholinesterase and antioxidant activities. PubChem fingerprint number 14, which represents the presence of one nitrogen atom in a compound contribute to biomarker and antifungal activities. This makes sense because the VOCs released in human breath are nitrogen containing such as dimethylamine and ammonia. Studies have shown elevated levels of inflammatory and oxidative stress biomarkers such as nitrogen oxides in patients with asthma, COPD, bronchiectasis and cystic fibrosis (Montuschi 2007; N.M. & M. 2008). It is also known that organonitrogen compounds containing an aliphatic nitrogen have significant antifungal properties (Mullen et al. 1989) and azole (a class of five-membered heterocyclic compounds containing a nitrogen atom and at least one other non-carbon atom as part of the ring) antifungal drugs are the most widely employed antifungal agents in clinical practice (Dodds-Ashley 2010). PubChem fingerprint number 839, which indicates the presence of complex SMARTS patterns, contribute to enhance plant growth and inhibit root growth.

These substructures or features have significant relationships with biological activities and are considered important for prediction of biological activities of VOCs.

4.4.5. Testing the recommended model on new datasets

It is important to show that the recommended fingerprint and machine learning method will also apply to other new datasets that have been not been part of the model building. Thus, 120 additional new VOC datasets were selected from other sources, which some of them were obtained from KNApSAcK Metabolite Activity DB and other VOC data were accumulated by literature search. Table 4.8 shows the new VOC data and predicted result by using our recommended model. We found that 73 VOC were predicted correctly, which give about 60.8% accuracy. The confusion matrix between actual and predicted biological activities is shown in Table 4.9. The low accuracy of prediction results is because of small sample of our training datasets, which is not sufficient enough for the model to learn and predict new data. Most of VOCs are predicted as biomarker, maybe because the training data was dominated by biomarkers. Also, 12 of the 14 odor VOCs were predicted as biomarkers. It is maybe because odor and biomarker VOCs are chemical structurally similar. It is recommended to increase the quantity of sample datasets so that the data for each of activity are well-balanced and this can increase the prediction accuracy.

Table 4.8. *List of new VOC datasets and predicted results.*

New VOC data	Actual Biological Activity	Predicted Activity
1,6-dioxacyclododecane-7,12-dione	Biomarker	Biomarker
Potassium lespedezate	Enhance plant growth	Enhance plant growth

4.5. Summary

In this chapter, we examined the classification of VOCs based on chemical structural similarity. The main reason is to find the relationships between chemical structures of VOCs and biological activities based on the *Similar Property Principle*, which states that molecules that are structurally similar are likely to have similar properties (Maggiara & Shanmugasundaram 2004). Based on heatmap clustering and hypergeometric distribution result, we found that there are strong links between chemical structure of VOCs and their biological activities. Additionally, we also compared several types of hierarchical clustering methods with DPPlus clustering to classify VOCs using fingerprint-based similarity measure between chemical structures. We extended our findings by building models using supervised machine learning methods to predict biological activities of VOCs based on chemical structures. We found that molecular fingerprints can be used for predicting biological activities of volatile metabolites. It is recommended to use PubChem and Combine fingerprint trained with Gradient Boosting Machine (GBM) method in the context of classifying VOCs. GBM method has advantage in term of computational speed and require less parameters for optimization, compared to other machine learning methods.

Conclusions

In order to obtain a better understanding of the relationships among species, VOC and biological activities, we utilized data-intensive science for discovering and identifying natural diversity of VOCs. This study has been started by accumulating VOC data from literature and also scientific reports. We found that many VOCs are produced by plants, microorganisms, insects and also human. Each of VOCs produced by different organisms are very unique and have its specific function or biological activities. This study is conducted in order to further investigate the relationships among organisms, emitting VOCs and their corresponding biological activities.

In this dissertation, we have discussed a database of VOCs emitted by various living organisms including microorganisms, fungi, plants, animals and humans, which can be accessed at KNApSAcK Metabolite Ecology Database. Apart from VOC biological activities related to human healthcare, more than half of the biological activities are associated with chemical ecology. Hierarchical clustering and graph clustering by DPCLUS algorithm were utilized to extract specific clusters of microorganism species based on VOC similarity. We found consistency between VOC and pathogenicity based classification of microorganisms. Additionally, we also compared several types of hierarchical clustering methods with DPCLUS clustering to classify VOCs using fingerprint-based similarity measure between chemical structures. Our research indicates that similar chemical structures of VOCs indicate possibilities of exhibiting similar biological activities. We extended our findings by using supervised machine learning methods to predict biological activities of VOCs

based on chemical structures. We have developed 72 classification model for the prediction of biological activities of VOCs by 9 types of fingerprints and trained by Deep Neural Network, Gradient Boosting Machine, Random Forest and Generalized Linear Model. Based on the computational results, PubChem fingerprints was suggested to be used as the input for the prediction, compared to other fingerprints. Gradient boosting machine (GBM) method can outperform Deep Neural Network (DNN) in term of classifying VOCs. GBM method has advantage in term of computational speed and require less parameters for optimization. Hence, we highly recommend to use Gradient Boosting Machine for the prediction of biological activities of VOCs based on chemical structures.

In future, more VOCs can be accumulated, and comprehensive analysis can be performed in the context of human healthcare and chemical ecology. The KNAPSAcK Metabolite Ecology Database may be useful for the discovery of novel agricultural tools and also for the non-invasive identification of biomarkers in the medical diagnostic field as well as a systematic research in various omics fields, especially metabolomics integrated with ecosystems. It is hoped that the KNAPSAcK Metabolite Ecology Database can be as a reference tool for the users to find information on volatile metabolites with related biological activities for the application in agriculture, ecosystems and healthcare industry.

5. Kang Liu, Azian Azamimi Abdullah, Ming Huang, Takaaki Nishioka, Md. Altaf-Ul-Amin, and Shigehiko Kanaya, 2017, Novel Approach to Classify Plants Based on Metabolite Content Similarity, *BioMed Research International*, Volume 2017 (2017), Article ID 5296729 (in Chapter 4).

International and domestic conferences

1. Yuki Ohtana, Azian Azamimi Abdullah, Md. Altaf-Ul-Amin, Ming Huang, Naoaki Ono, Tetsuo Sato, Tadao Sugiura, Hisayuki Horai, Yukiko Nakamura, Aki Morita (Hirai), Klaus W. Lange, Nelson K. Kibinge, Tetsuo Katsuragi, Tsuyoshi Shirai, and Shigehiko Kanaya, “Clustering of 3D-Structure Similarity Based Network of Secondary Metabolites Reveals Their Relationships with Biological Activities” GIW ISCB-ASIA 2014, 45, P86, Tokyo, Japan, December 16, 2014 (Poster Presentation) (in Chapter 2).
2. Azian Azamimi Abdullah, Md. Altaf-Ul-Amin, Takaaki Nishioka, Tetsuo Katsuragi, Naoaki Ono, Ammar Zakaria, Ali Yeon Md Shakaff and Shigehiko Kanaya, “Analysis of Volatile Metabolites Emitted by Various Species to Reveal Their Roles in Chemical Ecology and Healthcare”, 2015 2nd International Conference on Biomedical Engineering (ICOBE 2015), 30-31st March, Penang, Malaysia (Oral Presentation) (in Chapter 2).
3. Azian Azamimi Abdullah, Md. Altaf-Ul-Amin, Aki Hirai Morita, Tetsuo Sato, Tadao Sugiura, Naoaki Ono, Takaaki Nishioka and Shigehiko Kanaya, “KNApSACk Metabolite Ecology Database for Investigating the Relationships Between VOCs and Biological Activities”, 11th International Conference of the Metabolomics Society (Metabolomics 2015), 29th June – 2nd July 2015, San Francisco, California, USA (Poster Presentation) (in Chapter 2, 3 and 4).
4. Azian Azamimi Abdullah, Shigehiko Kanaya and Md Altaf-Ul-Amin, “Development and Mining of a Volatile Organic Compound (VOC) Database”, 11th Asian Conference on Chemical Sensors (ACCS2015), 16-18th November 2015, Penang, Malaysia (Oral Presentation) (in Chapter 2, 3 and 4).
5. Azian Azamimi Abdullah, Md Altaf-Ul-Amin, Naoaki Ono, Nurlisa Yusuf, Ammar Zakaria, Takaaki Nishioka, Shigehiko Kanaya, “Comparison of

- Clustering Methods in the Context of Chemical Structure Similarity Based Classification of VOCs”, 11th Asian Conference on Chemical Sensors (ACCS2015), 16-18th November 2015, Penang, Malaysia (Oral Presentation) (in Chapter 4).
6. Md. Altaf-Ul-Amin, Kang Liu, Azian Azamimi Abdullah, Aki H. Morita, Makio Shiraishi and Shigehiko Kanaya, “Classification of plants based on chemical structural similarity of metabolite contents obtained from KNApSAcK database”, Applied Bioinformatics in Life Sciences, 17-18th March 2016, Leuven, Belgium (Poster Presentation) (in Chapter 4).
 7. Azian Azamimi Abdullah, Md. Altaf-Ul-Amin, Ammar Zakaria and Shigehiko Kanaya, “Prediction of Biological Activities of Volatile Metabolites Using Deep Learning”, 15th International Conference On BioInformatics (InCOB 2016), 21-23 September 2016, Biopolis, Singapore (Short Oral and Poster Presentation) (in Chapter 4).
 8. Azian Azamimi Abdullah, “Comprehensive Understand of Relationship Among Species, Volatile Organic Compound, and Biological Activity”, 39th Symposium on Chemoinformatics, 29-30 September 2016, Hamamatsu, Shizouka, Japan (Oral Presentation) (in Chapter 2, 3 and 4).

Awards

1. Molecular Informatics 2014 Best Paper Award

Yuki Ohtana, Azian Azamimi Abdullah, Md Altaf-Ul-Amin, Ming Huang, Naoaki Ono, Tetsuo Sato, Tadao Sugiura, Hisayuki Horai, Yukiko Nakamura, Klaus W Lange, Nelson K Kibinge, Tetsuo Katsuragi, Tsuyoshi Shirai, Shigehiko Kanaya, “Clustering of 3D-Structure Similarity Based Network of Secondary Metabolites Reveals Their Relationships with Biological Activities”, Molecular Informatics 2014, 33(11-12), 790-801.

2. INCOB 2016 Best Poster Award (Silver)

Azian Azamimi Abdullah, Md. Altaf-Ul-Amin, Ammar Zakaria and Shigehiko Kanaya, “Prediction of Biological Activities of Volatile Metabolites Using Deep Learning”, 15th International Conference On BioInformatics (InCOB 2016), 21-23 September 2016, Biopolis, Singapore.

Appendix B

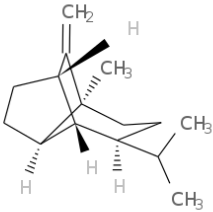

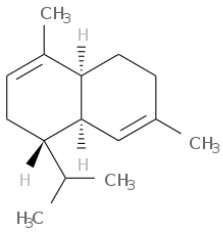

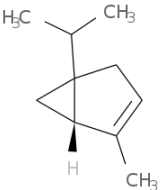

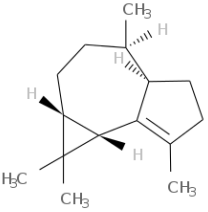

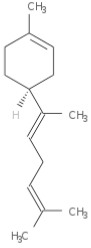

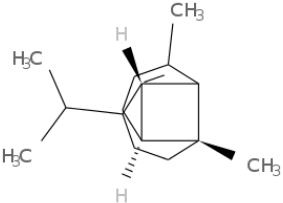

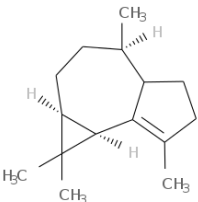

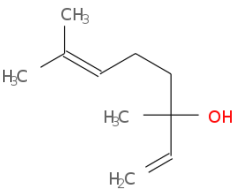

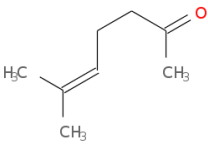

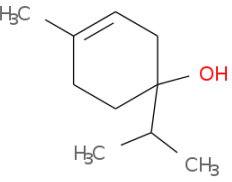

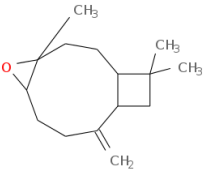

Chemical structures of the VOCs belonging to all clusters (Cluster 1 to Cluster 11), as mentioned in Chapter 4.

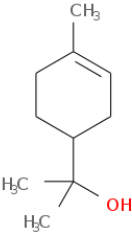

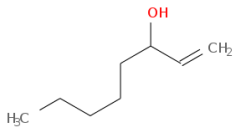

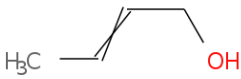

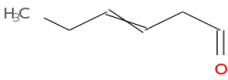

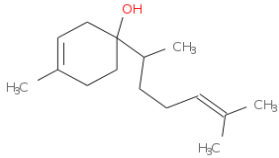

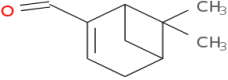

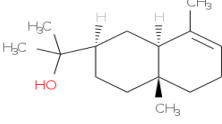

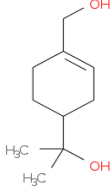

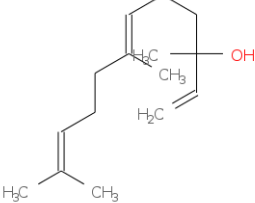

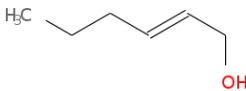

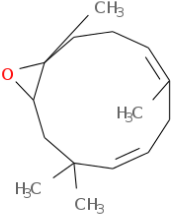

Cluster 1 (55 VOCs)			
 <p>C00000805 Alpha-Pinene</p>	 <p>C00020376 beta-Guaiene</p>	 <p>C00003051 alpha-Phellandrene</p>	 <p>gamma-Terpinen</p>
 <p>C00003060 alpha-Terpinene</p>	 <p>C00010872 abeta-Phellandrene</p>	 <p>Terpinolene</p>	 <p>C00000816 beta-Pinene</p>
 <p>C00003118 Copaene</p>	 <p>C00010868 d-Limonene</p>	 <p>(+)-2-Carene</p>	 <p>a-Elemene</p>

 <p>(E)-alpha-Bergamotene</p>	 <p>C00012011 delta-Elemene</p>	 <p>C00021230 Aromadendrene</p>	 <p>C00003204 alpha-Zingiberene</p>
 <p>C00003194 Thujopsene</p>	 <p>C00003162 Longifolene</p>	 <p>(+)-Limonene</p>	 <p>C00000806 (-)-beta-Pinene</p>
 <p>1-alpha-Pinene</p>	 <p>C00007636 delta-Cadinene</p>	 <p>C00021999 Seychellene</p>	 <p>Sesquiphellandrene</p>

 <p>C00007634 delta-Selinene</p>	 <p>C00021309 alpha-Himachalene</p>	 <p>Cadinene</p>	 <p>Dehydroaromadendrene</p>
 <p>C00017471 Aristolene</p>	 <p>(+)-4-Carene</p>	 <p>C00037332 Isoledene</p>	 <p>alpha-Panasinsen</p>
 <p>C00003110 beta-Caryophyllene</p>	 <p>C00012474 Isocaryophyllene</p>	 <p>C00021580 beta-Acoradiene</p>	 <p>(-)-Germacrene D</p>

 <p>C00003110 Caryophyllene</p>	 <p>alpha-Bisabolene</p>	 <p>C00011720 Caryophyllene</p>	 <p>2-Menthene</p>
 <p>4,11-Selinadiene</p>	 <p>C00003111 alpha-Cedrene</p>	 <p>C00012012 gamma-Elemene</p>	 <p>C00007453 beta-Elemene</p>
 <p>C00011719 Germacrene A</p>	 <p>C00034741 Valencene</p>	 <p>C00021229 Alloaromadendrene</p>	 <p>C00016975 Eremophilene</p>

 <p>(+)-Sativene</p>	 <p>C00029671 alpha-Muurolene</p>	 <p>C00000184 alpha-Thujene</p>	 <p>C00021227 alpha-Gurjunene</p>
 <p>C00050259 Trans-alpha-bisabolene</p>	 <p>C00003118 alpha-Copaene</p>	 <p>Gurjunene</p>	
<p>Cluster 2 (33 VOCs)</p>			
 <p>beta-Linalool</p>	 <p>C00034775 6-Methyl-5-hepten-2-one</p>	 <p>C00029544 Terpinen-4-ol</p>	 <p>C00012483 Caryophyllene oxide</p>

 <p>p-Menth-1-en-8-ol</p>	 <p>C00029423 1-Octen-3-ol</p>	 <p>2-Buten-1-ol</p>	 <p>C00048948 3-Hexenal</p>
 <p>beta-Bisobolol</p>	 <p>C00030803 Myrtenal</p>	 <p>C00000163 alpha-Eudesmol</p>	 <p>p-Menth-1-en-8-ol</p>
 <p>2-Undecenal</p>	 <p>C00003166 Nerolidol</p>	 <p>2-Hexenol</p>	 <p>C00012443 Humulene epoxide</p>

 <p>E-2-Methyl-3-tetradecen-1-ol acetate</p>	 <p>Z,Z-2,5-Pentadecadien-1-ol</p>	 <p>C00020065 alpha-Cadinol</p>	 <p>C00035852 Limonene oxide</p>
 <p>(2E,6E)-2,6-Nonadienoic acid</p>	 <p>1-Penten-2-on</p>	 <p>C00020282 Drimenol</p>	 <p>C00003252 Drimenin</p>
 <p>C00001232 Oleic acid</p>	 <p>C00033734 Cubenol</p>	 <p>Longipinocarvone</p>	 <p>Geranylacetone</p>

 <p>C00029336 (E)-Geranyl acetone</p>	 <p>Z-3-Octadecen-1-ol acetate</p>	 <p>C00003467 Phytol</p>	 <p>C00001229 Myristoleic acid</p>
 <p>(E)-2-Hexenal</p>			
Cluster 3 (41 VOCs)			
 <p>C00035857 Octane</p>	 <p>Isobutane</p>	 <p>2-Methylbutane</p>	 <p>2-Methylpentane</p>

 <p>C00035853 Methylcyclohexane</p>	 <p>Pentane</p>	 <p>Hexane</p>	 <p>C00007453 Cyclohexane</p>
 <p>C00034882 Nonane</p>	 <p>C00001248 Dodecane</p>	 <p>C00030165 Eicosane</p>	 <p>Heptane</p>
 <p>2,3,3-Trimethylpentane</p>	 <p>C00050708 3-Methylhexane</p>	 <p>1,4- Dimethylcyclohexane</p>	 <p>C00035484 2-Methylhexane</p>

 <p>C00030879 Octadecane</p>	 <p>C00001265 Pentadecane</p>	 <p>C00030472 Heptadecane</p>	 <p>C00030827 Nonadecane</p>
 <p>Phytane</p>	 <p>C00032307 Tetracosane</p>	 <p>2,4-Dimethylheptane</p>	 <p>3-Methylundecane</p>
 <p>C00032443 Undecane</p>	 <p>C00048375 Decane</p>	 <p>4-Methyloctane</p>	 <p>4-Methyl decane</p>

 <p>2-Methyloctane</p>	 <p>1-Chlorooctadecane</p>	 <p>Trans-anti-1-methyl-decahydronaphthalene</p>	 <p>2,2,4-Trimethylheptane</p>
 <p>Alkanes</p>	 <p>8-Isoprostane</p>	 <p>4-Methyltridecane</p>	 <p>5-Methyltridecane</p>
 <p>4-Methyldodecane</p>	 <p>Methylcyclododecane</p>	 <p>2,5,6-Trimethyloctane</p>	 <p>Pentamethylheptane</p>

 <p>2,3,4,5,6-Pentamethylheptane</p>			
Cluster 4 (18 VOCs)			
 <p>C00046784 Isoprene</p>	 <p>2,4,4-Trimethyl-1-pentene</p>	 <p>2-Pentadiene</p>	 <p>4,4-Dimethyl-1-pentene</p>
 <p>1-Undecene</p>	 <p>1-Eicosene</p>	 <p>2-Hexene</p>	 <p>C00000853 Myrcene</p>

 <p>3-Octene</p>	 <p>3,3-Dimethylhex-1-ene</p>	 <p>1,4-Pentadiene</p>	 <p>Tricosene</p>
 <p>C00003131 beta-Farnesene</p>	 <p>C00003147 alpha-Caryophyllene</p>	 <p>Ocimene</p>	 <p>C00029335 beta-Ocimene</p>
 <p>2-Octene</p>	 <p>2-Methylbut-1-ene</p>		

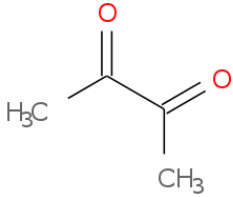

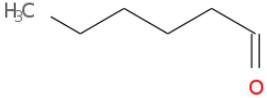

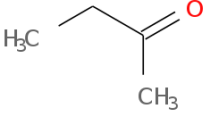

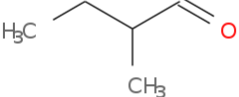

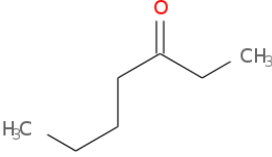

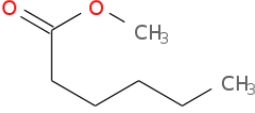

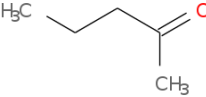

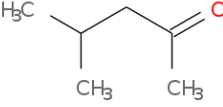

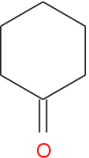

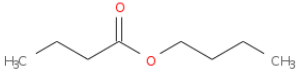

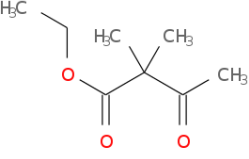

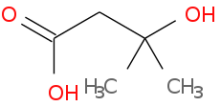

Cluster 5 (21 VOCs)			
 <p>C00030880 Octanal</p>	 <p>Hexadecanoic acid</p>	 <p>Dodecanoic acid</p>	 <p>C00001238 Octadecanoic acid</p>
 <p>Isopropyl myristate</p>	 <p>C00030099 Decanal</p>	 <p>C00032442 Undecanal</p>	 <p>Dodecanal</p>
 <p>C00001228 Tetradecanoic acid</p>	 <p>C00029463 2-Nonanone</p>	 <p>6-Methylheptan-2-one</p>	 <p>C00007423 Pentadecanoic acid</p>

 <p>C00030959 Pentadecanal</p>	 <p>Ethyl cyclohexanecarboxylate</p>	 <p>Methyl cyclohexanecarboxylate</p>	 <p>p-Menthone</p>
 <p>C00030828 Nonanal</p>	 <p>Butyl cyclohexanecarboxylate</p>	 <p>Propyl cyclohexanecarboxylate</p>	 <p>Octan-3-one</p>
 <p>4-Trifluoroacetoxypentadecane</p>			

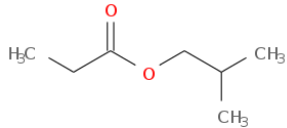

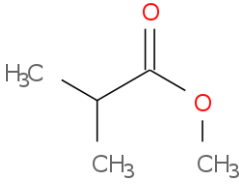

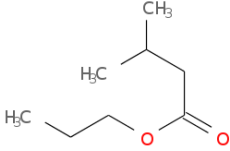

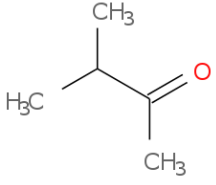

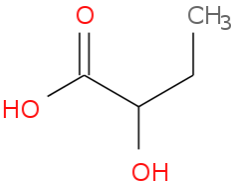

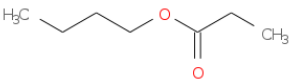

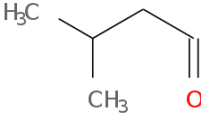

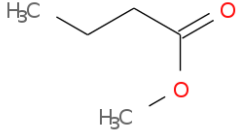

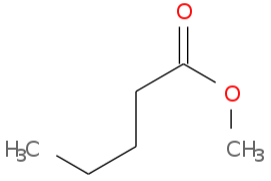

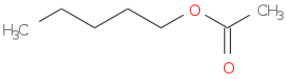

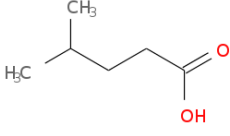

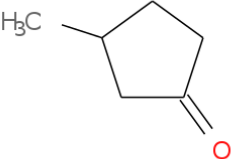

Cluster 6 (25 VOCs)			
 <p>C00050411 2,3-Butanediol</p>	 <p>1-Butanol</p>	 <p>Propanol</p>	 <p>S-Methyl 3-methylbutanethioate</p>
 <p>2-Propanol</p>	 <p>Pentanol</p>	 <p>3-Methyl-1-butanol</p>	 <p>2-Methyl-1-propanol</p>
 <p>2-Butanol</p>	 <p>1,3-butanediol</p>	 <p>C00030100 Decanol</p>	 <p>C00030152 1-Dodecanol</p>

 <p>C00050415 2-Methyl-1-butanol</p>	 <p>3-Pentanol</p>	 <p>C00035495 3-Octanol</p>	 <p>Isobutylether</p>
 <p>2-Dodecyloxirane</p>	 <p>2-Pentanol</p>	 <p>1-Hexadecanol</p>	 <p>Butane-1-methoxy-3-methyl</p>
 <p>2,4-Dimethylpentane</p>	 <p>3-Sulfanyl-pentan-1-ol</p>	 <p>3-Sulfanylhexan-1-ol</p>	 <p>2-Methyl-3-sulfanylbutan-1-ol</p>

 <p>3-Methyl-3-sulfanyln-hexan-1-ol</p>			
Cluster 7 (47 VOCs)			
 <p>Acetate</p>	 <p>Acetic acid</p>	 <p>C00007392 Acetaldehyde</p>	 <p>C00050424 Acetoin</p>
 <p>C00048304 Acetone</p>	 <p>Butanoic acid</p>	 <p>C00050492 Propanal</p>	 <p>Propanoic acid</p>

 <p>C00050437 2,3-Butanedione</p>	 <p>C00000357 Hexanal</p>	 <p>2-Butanone</p>	 <p>2-Methylbutanal</p>
 <p>3-Heptanone</p>	 <p>Methyl hexanoate</p>	 <p>2-Pentanone</p>	 <p>C00051562 Methyl isobutyl ketone</p>
 <p>Cyclohexanone</p>	 <p>1-Chloro-3-methylbutane</p>	 <p>Ethyl 2,2-dimethyl-3-oxobutanoate</p>	 <p>3-Hydroxyisovaleric acid</p>

 <p>C00050478 Lactic acid</p>	 <p>2-Hydroxybutyrate</p>	 <p>Butyl (2R)-2-methylbutanoate</p>	 <p>2-Methylbutanoate</p>
 <p>Pentanoic acid</p>	 <p>Pentanal</p>	 <p>Heptanal</p>	 <p>C00029461 2-Methylbutanoic acid</p>
 <p>C00001308 Ethyl acetate</p>	 <p>C00001189 3-Methylbutanoic acid</p>	 <p>Ethyl valerate</p>	 <p>2-Methylpropyl butanoate</p>

 <p>2-Methylpropyl propanoate</p>	 <p>Methyl 2-methylpropanoate</p>	 <p>Propyl 3-methylbutanoate</p>	 <p>3-Methyl-butan-2-one</p>
 <p>alpha-Hydroxybutyric acid</p>	 <p>Butyl propanoate</p>	 <p>C00048949 3-Methyl-butanal</p>	 <p>Methyl butanoate</p>
